## THE CAMBRIDGE MEETING

As the two Annual Meetings before the last two wars were held at Aberdeen, it was fitting that the first normal post-war Meeting should again be held at Cambridge after a lapse now of twenty-eight years. Those who planned the Meeting were a short time ago worried lest present pre-occupations with the National Health Service, difficulties of travel by car, food rationing, shortage of accommodation, and a host of other inconveniences would discourage members from attending. The President of the Meeting, Sir Lionel Whitby, who himself did so much preparatory work for it, must have been reassured by the crowds that thronged the reception he gave in the Old Schools on Tuesday, June 29. In the past town and gown have had their differences of opinion, but to-day the old conflicts are but a memory, and Sir Lionel's efforts were energetically backed up by Councillor G F Hickson, M A, the Mayor of Cambridge, who welcomed the B M A on the first day. The task of organizing a large Meeting was difficult enough in the lush days of peace. This year hitches might have been expected, not only because of the obvious hindrances but also because the President and his helpers from the Cambridge and Huntingdon Branch had not had the opportunity of being coached at the Meeting normally held the previous year. But many with long experience of Meetings commented on the remarkably efficient organization of this the 116th Annual Meeting of the B M A. That it was so successfully conducted, and so happily concluded, was due to the wise leadership, unflagging energy, and unfailing courtesy of Sir Lionel Whitby, who put us still deeper in his debt by delivering in the Senate House on the evening of his reception a Presidential Address that made the occasion an inspiration. In this Address, delivered on the eve of the appointed day for the National Health Service Act, Sir Lionel hoped there would "always be elbow room for a man to work out his own ideas, to be outspoken in criticism and debate, and to be free from unnecessary restrictions, regulations, and regimentation." "Let us hope also," he added, "that men may still be inspired to undertake work for the love of it." These were suitable words to be addressed to men and women meeting in a university which has for centuries enabled men of genius to follow the argument wherever it should lead.

During the eight days between June 25 and July 2 the familiar pattern of an Annual Meeting was followed—a pattern which now almost has the quality of a ritual. The first three and a half days were taken up with the debates of the Annual Representative Meeting. These concluded, the Annual General Meeting was held, and the retiring President, Sir Hugh Lett, invested Sir Lionel Whitby with the Presidential Badge of Office, prefacing this act with a delightful speech in which he informed the Meeting of

some of the outstanding facts in their new President's career. The Meeting, too, was told that the President for next year is to be Dr C W Curtis Bain, physician to the Harrogate General Hospital. This concluded the business on Tuesday—a day given to the principal ceremonies which divide the business from the scientific side of the eight days conference. In the afternoon medical men and women in their gowns and robes walked in procession to Great St Mary's Church for the official religious service. This was followed by the reception at Christ's College held by the Vice Chancellor, Canon C E Raven to whom the Meeting was indebted for the gracious welcome given to it by the University. The last three days were devoted to the proceedings of the nineteen scientific Sections in one of the most instructive programmes yet drawn up for an annual meeting. The papers read will be published in a special volume of Proceedings, and it is hoped as well to print a few of them in the much restricted pages of this *Journal*. Many of the discussions are reported in this week's issue. This is not the place to enumerate the many interesting themes presented by men speaking with authority, but it will not be thought invidious if we refer in particular to the generosity of that doyen of medical science, Sir Henry Dale, O M, who not only opened the discussions at two Section meetings but also on Friday night gave the popular lecture, which entranced his listeners.

Our hosts at Cambridge have set a standard for Annual Meetings which we hope will serve as a model for future years. Few places, indeed, can offer to medical men the rich and varied attractions of an ancient university town. But Cambridge has shown that dignity and learning are not incompatible with enjoyment and grace of living as exemplified in such delightful fashion throughout the meeting by Sir Lionel and Lady Whitby. In Cambridge tradition is a living force which is an inspiration to those working in advanced fields of science. Very many of its students are supported out of public funds, as in part is the University itself. Yet both preserve that intellectual freedom so essential to the advancement of knowledge. Here is a pattern which the world of Medicine may try to follow in the coming years.

## SOME POINTS OF DEBATE

The report of the Annual Representative Meeting was published in last week's *Supplement* and is concluded this week. Once more 372 Representatives were provided with an annual occasion to be "outspoken in criticism and debate." At the start there was a motion from the Metropolitan Counties Branch condemning the method of block voting for elections of the Council and Standing Committees. This brought into the open a grouse that has for some years been voiced in those informal conversations that are such an attractive part of a large conference. The motion was carried by 124 votes to 90 and it may be presumed that block voting will disappear at next year's A R M. There was a further move to criticize the Council for the conduct of the profession's case during the past twelve months. It could not, of course, be expected that

such a vast change in the life of the profession as is inevitable under the National Health Service Act should be introduced without feelings of anxiety and discontent among medical men. To set up a committee of inquiry, as was moved, would at the best have been a waste of time, but it is nevertheless better that such criticism should come into the open rather than be left to rankle unheard. Indeed, the fact that there was so little support for the motion moved by Dr Breach showed that the Representative Body, reflecting opinion in the profession generally, has sustained its desire for a comprehensive medical service for the whole community in a scheme which we believe gives doctors "elbow room for a man to work out his own ideas."

The two matters which stood out in the A R M debates were the Association's plans for the organization of consultants and specialists and the question of trade union status. The discussion on these two important matters was fully reported in the *Supplement* of last week. The plan for the first of these was most ably presented by Mr A M A Moore, Chairman of the Consultants and Specialists Committee, and appointed at the Meeting as the Treasurer for 1948-51. The Representatives agreed to the important proposal that in the B M A's scheme consultants and specialists should have complete autonomy, and when Mr Ross Smith brought forward a motion to this effect Dr H Guy Dain, the Chairman of Council, said that this was acceptable to the Council of the B M A. The second point stressed by Mr Moore was on the proportions of teachers and non-teachers on the Central Committee. In the discussions that had taken place the provincial teaching hospital staffs had felt that they would be out-voted on the new Central Committee. In view of this the Non-undergraduate Teaching Association and the Provincial Teachers Association had agreed to equal representation—a most satisfactory outcome.

Under the heading of "Future Organization of the Association" on the agenda paper were a number of motions on the theme of the first—"that the British Medical Association explore the possibility of setting up a body equivalent to a trade union." After some discussion on this it was agreed to refer the matter to Council. The merits of the case will have to be gone into with great care before the matter is once more presented to the Representative Body, but it is as well to reflect that the strength and influence of the B M A reside largely in the fact that it is a voluntary organization, and that in the future the appeal to its members of a voluntary body will in a planned society be even stronger than it has been in the past.

### RETIREMENT FROM OFFICE

Last week two of the principal officers of the British Medical Association relinquished the responsible posts which they have for many years held with much distinction and ability, years of testing and trial that have greatly added to the burden of responsibility which those in high office must always carry. Dr J B Miller, who is succeeded by Dr E A Gregg, has been Chairman of the Representative Body for three strenuous years, during which no fewer than seven Representative Meetings have been held. During the forty years of its history the Representative Body has had no more exacting time than the past three. In an atmosphere often tense with political uncertainties it has

had to make momentous decisions affecting the future of the medical profession. That it has acquitted itself of its hard task with decorum and wisdom has been in large measure due to the firm but tolerant conduct of its debates by Dr Miller, who has known when to use his gift of humorous interjection as a solvent of tension. It is safe to say that during his stormy years of office he has made many friends and no enemies, no mean tribute to his sterling character. Dr John W Bone had made known his wish to retire from the office of Treasurer, and is succeeded by Mr A M A Moore. Recognition of his long years of devoted service to the B M A, and especially of his nine years' treasurership, was made at the Meeting last week by the award to him of the Gold Medal of the Association, the highest honour it can bestow. Dr Bone's remarkable grasp of the business of any meeting, whether of committee or of Council, admirably fitted him for the control of the complex finances of a large organization. And he has had to exercise this control during the difficult war years. Under his pertinacious and skilful guidance the financial position of the Association has been greatly strengthened, and he hands on to his successor a clean balance-sheet.

It is well to record that the two distinguished officers of the Association who now retire have given it without stint long years of hard work without monetary reward. Their service has been voluntary, and their reward, we may be sure, the satisfaction of work well done and the high esteem in which they are held by their professional colleagues.

### HEALTH OF ARC WELDERS

Since Doig and McLaughlin<sup>1</sup> drew attention in 1936 to siderosis in arc welders much has been written on the subject. First Enzer and Sander<sup>2</sup> reported the histological findings in the lungs of an arc welder exhumed eighteen months after death, they showed that the radiological shadows were caused by deposits of iron in the peribronchial and periarterial lymph spaces and that there was no fibrosis in the lung. Enzer, Simonsen, and Evans<sup>3</sup> then showed that the deposits caused no demonstrable disability or reduction in vital capacity. This year the original authors<sup>4</sup> have followed up their cases and found that the iron has been got rid of and that the radiological shadows have become less evident. Our knowledge of arc welders siderosis, apart from its morbid anatomy, now seems to be fairly complete, but it is remarkable that in these twelve years no pathologist has been able to describe the findings at a recent necropsy on an arc welder.

Arc welding became very important during the war, and the United States Public Health Service<sup>5</sup> has recently issued a report on the health of arc welders in steel-ship construction. This is based on a survey carried out in 1944 on 4,650 men and women working in seven shipyards on the Atlantic, the Mexican Gulf, and the Pacific coasts. The fume to which the workers were exposed was analysed. As might be expected, it was highest in the most confined welding spaces, but it contained more than 30 mg of ferric oxide per cubic metre of air for all welding locations and more than 15 mg of zinc oxide per cubic metre in several. The fume consists mostly of ferric oxide 50%, titanium dioxide 15%, silica 8%, and a mixture of acid-soluble metals such as magnesium, calcium, aluminium, manganese, chromium, copper, and sodium. More than half the samples of gas were found to contain fewer than 5 parts per million of nitrogen oxides.

<sup>4</sup> *Lancet* 1948 1 789

<sup>5</sup> *Public Health Bulletin* No 298, U.S. Public Health Service

Diseases other than welders' siderosis found in the group included metal-fume fever—chiefly among men working on galvanized metal and piping. Conjunctival irritation was prevalent, and though actinic conjunctivitis ("flashed eyes") was found infrequently many workers reported having been affected at some time in the past. Nasal congestion, pharyngitis, and upper respiratory symptoms were more prevalent among welders who used tobacco than among those in a control group. There were 371 (81%) shipyard workers who showed evidence of calcified primary tuberculosis, while the incidence of reinfectious tuberculosis was 1.3%. Possibly a selective influence kept people with tuberculosis away from welding. Rheumatic heart disease was found in 1.6% of the male shipyard workers, and the incidence of arteriosclerotic hypertensive heart disease was 5.4% in white male welders, compared with 17.9% in a similar group of non-welders. As welding fumes may potentially produce anaemia, full blood examinations were carried out, but the results showed no difference between welders and non-welders. However, there was some evidence to suggest that men welding galvanized metal and exposed to zinc fumes are more likely to have abnormal sedimentation rates than those not so exposed. This sign may be a prodrome of zinc chill.

Slag burns or scars were characteristic occupational stigmata. They were most commonly observed on the antero-lateral aspect of the elbow just lateral to the cubital fossa. Right-handed welders showed the lesion on the left arm and left-handed welders on the right arm. They were also found around the ankles, along the belt line of the abdomen, and in the episternal region. The burns were often in a stage of indolent ulceration showing a dirty granulating base. A recent small burn often looked rather like a doughnut, for the lesion was a ring of vesiculation enclosing a tiny area of seared skin. Dressings were not often applied, and severe secondary infection was rare. These burns were commonest in the most experienced welders doing overhead work.

### FOOD PRESERVATION

With the growth of cities more and more people are depending on food that has been kept, and because of the scarcity of food throughout the world and of the special nutritive value of perishable food it has become essential to preserve the surpluses produced in glut periods for use later. Methods of preservation must be based on a knowledge of the composition of foodstuffs and of the changes that take place when they are kept or processed. Research on these problems is undertaken by the Food Investigation Board, and a report on the Board's work during the years 1940-1946 has been published by the Department of Scientific and Industrial Research<sup>1</sup>.

The preservation of food in good condition does not depend only on killing off micro organisms or on preventing their growth and activity, since fresh foods are not wholly dead. Meat and vegetables contain enzymes, while complicated metabolic changes occur in fruit. In preservation either of two lines may be followed: the foodstuff may be completely killed by heat and its condition fixed, as is done when fruit is canned, or the metabolic processes may be controlled in order that the food may remain palatable. In dehydration, which was the chief study of the Food Board during the war, the first line must be taken, without the preliminary scalding dehydrated vegetables are tough and of poor quality, and their ascorbic acid is destroyed by oxidase. Dried milk keeps much better if the milk is pasteurized at a higher temperature than normal before drying.

Killing micro-organisms and enzymes is not enough to prevent deterioration. Unless the water content is reduced to below 5% vegetables lose their colour and ascorbic acid. For prolonged storage oxygen must be removed, otherwise the carotene of vegetables and the fats of dried milk are oxidized. Each foodstuff presents its special problems. The biological value of the proteins of dried milk falls on keeping. This is due to the combination of free amino groups, mainly lysine, with reducing sugars. The production of "off colour" in dried carrots is due to the presence of heavy metal salts. The deterioration of spray-dried egg is mainly due to the presence of glucose, the glucose can be removed by fermentation with yeast.

Cold instead of heat can be used to stop metabolism and the growth of micro organisms in fish. The use of quick freezing at all the main ports should give a constant flow of supplies to consumers. One firm is planning to freeze fish at sea, so that the whole catch will be landed fresh however long the voyage.

To preserve fruit the control of metabolic processes may be necessary. The functional disease of apples known as "scald" is related to the concentration of volatile compounds produced, at present the practical method of controlling this disease is to wrap the fruit in paper impregnated with mineral oil. Temperature influences the metabolism of stored fruit. Cox's Orange Pippins after the skin has been coated with oil keep best at 40° F (4.4° C). Low temperatures upset the metabolism of plums, peaches, bananas, and tomatoes. Storage at 31° F (-0.6° C) for longer than 3 weeks causes "internal browning" of Victorian plums. But if the cold storage is broken by a period of 2 or 3 days at 65° F (18.4° C) the plums can be kept for 35 to 40 days. The ripening mechanism of immature tomatoes is damaged by exposure to temperatures below 50-55° F (10-13° C).

New methods of conservation will cut down waste and give us wholesome foodstuffs of good quality, but those who remember food as it was in small market towns 50 years ago will view the changes with mixed feelings. The standardized butter of to-day is better than the average butter made under insanitary conditions by farmers' wives of varying skill, but it will not compare with the best butter of those days, with its slight flavour of wood smoke. Shop eggs are much worse than they were then, for with two markets a week no egg was over a week old. Now the majority are unable to buy new-laid eggs by honest means and egg powder, however skilfully preserved, is no substitute for fresh eggs. There is a danger that the new methods may lead to loss of variety and to acceptance of a standardized second best.

### ROSS JUBILEE

In the *British Medical Journal* of Dec 18, 1897, Surgeon Major Ronald Ross, I.M.S., contributed an article entitled "On Some Peculiar Pigmented Cells found in Two Mosquitoes fed on Malarial Blood," in which he described how he found "certain remarkable and suspicious cells containing pigment identical in appearance to that of the parasite of malaria." Ross forwarded his preparations to the Editor of the *Journal* who submitted them for examination to Dr. Thin, Mr. Blind Sutton, and Dr. Patrick Manson. Manson, in a note to Ross's article, wrote, "There can be no question that these cells contain a pigment optically indistinguishable from the pigment which is so characteristic a feature in the malaria parasite. I am inclined to think that Ross may have found the extra-corporeal phase of malaria. If this be the case, then he has made a discovery of the first importance." In the *Journal* of June 11, 1898 Dr. Patrick Manson contributed an article on Ross

<sup>1</sup> Food Investigation 1940 to 1946. London 1948. H.M.S.O. Price 9d. net.

investigations, in order, as he put it, "First, again to call the attention of workers in malaria to this promising field for investigation, secondly, to place on record Ross's claims to priority in discovery, and lastly, to vindicate myself from the charge of unscientific and unwarrantable speculation" Manson had recorded his "speculation" in the Goulstonian lectures printed in this *Journal* in 1896. This week the London School of Hygiene and Tropical Medicine, and the Ross Institute of Tropical Hygiene, celebrated the Jubilee of Ross's discovery.

### CANCER CELLS IN SPUTUM AND URINE

The increasing use of the biopsy has proved to pathologists how valuable their contribution can be to the problem of the early diagnosis of malignancy, in spite of the fact that the material submitted for examination is of necessity often very poor in quality and very small in quantity. Yet even the smallest specimens, including those taken by the needle and syringe, may yield surprisingly good results. Is it sound pathology to take a further step and consider the possibility of diagnosing malignant disease by discovering a few isolated clusters, each perhaps composed of 20 to 30 cells, in films of the sputum or urinary deposit?

The first serious attempt to answer this question was made at St Thomas's Hospital in 1935 by Dudgeon and Wrigley,<sup>1</sup> who were able to demonstrate malignant cells in the sputum in 68% of patients with proved bronchogenic carcinoma (in a series of 58 cases). Barrett<sup>2</sup> and Gower<sup>3</sup> reported positive results in 68% and 64% respectively. A very complete study was published by Wandall,<sup>4</sup> of Copenhagen, in 1944, out of 100 proved cases positive results were obtained in 84. In this series 82 of the patients were examined by bronchoscopy, it is significant that a positive diagnosis as a result of examination of biopsy specimens could be made in only 55%. By combining both methods Wandall was able to make a correct diagnosis of malignancy in 94% of proved cases. The percentage of false positives in a series of 193 sputum examinations was 3.1. Herbut and Clerf<sup>5</sup> examined the bronchial secretion removed by bronchoscope in 57 proved cases of bronchogenic cancer, and found cancer cells in 82.4%, examination of biopsy specimens gave positive results in only 42%, but a combination of both methods provided a positive diagnosis in 92.5%. It seems probable that bronchial secretion may prove to be more suitable material than sputum, it has the added advantage that if the biopsy material is a poor sample, or if for various reasons material is not removed, the growth can often be accurately localized.

The work has been carried a stage further by Woolner and McDonald<sup>6</sup> at the Mayo Clinic. They point out that negative results are to be expected in the small group of patients in whom the growth is peripheral, especially if it has not opened into the airways, and also in the very large majority of cases of bronchial adenoma and cylindroma. Diagnosis from sputum examination is rather more difficult in the mucus-secreting adenocarcinomata, but is of great value in tumours arising in a large, upper-lobe bronchus out of reach of the bronchoscope.

"False positives" are recorded in from 1 to 3% of sputum examinations. A few of these were obtained in cases of chronic pulmonary infection with incomplete resolution and squamous metaplasia of the bronchial epithelium but the majority are most probably due to lack of experience with the method. The investigation must be conducted by a morbid histologist. It demands not only an intimate knowledge of the cytology of malig-

nant growths in general and of the perplexing variations in structure which are encountered in bronchial cancer, but also a period of apprenticeship in the study of the finer cytology of the sputum in non-malignant pulmonary disease and the appearances of malignant cells in film preparations made from the surface of all varieties of primary bronchial neoplasms. The specimen must be examined without delay, if this is unavoidable it should be collected in 10 ml of absolute alcohol. A minimum of five films from one specimen must be made. If clinical evidence is sufficiently in favour of neoplasm several specimens of sputum should be examined. All those who have had experience in the method agree that a positive diagnosis must rest on finding several clusters of malignant cells in the specimen. The clusters must be composed of cells which are fresh enough to show nuclear detail, so that the chromatin network and nucleoli are clearly displayed. The clusters must also be large enough for variations in nuclear shape, size, and depth of staining to be visible.

Accompanying Woolner and McDonald's paper are two others on the identification of malignant cells in urinary sediment. The first, by Daut and McDonald,<sup>7</sup> records an investigation of forty consecutive cases of genito-urinary disease. In nineteen of these, subsequently proved to be suffering from malignant disease, carcinoma cells were found in the urinary deposit. In the second paper Ludden and McDonald<sup>8</sup> describe the appearance of malignant cells in smears of sediment from the urine of patients with malignant disease of the kidney. Neither of these papers is convincing enough to justify the routine use of the method, but both are sufficiently encouraging to stimulate further investigation.

### THE EXCRETION OF ANTIMONY

There has hitherto been little precise information about the excretion of antimony compounds, which are widely used in the treatment of schistosomiasis. In this disease tartar emetic or an organic antimonial compound is injected intravenously. To be effective a course of injections, commonly on alternate days, must be given. Antimony compounds differ in this respect from an arsenic compound such as neoarsphenamine, which is given once a week, but resemble mapharside, which is often given daily. It is known that mapharside is much more rapidly excreted than neoarsphenamine, as is to be expected from the smaller size of its molecule. It might be assumed, therefore, that antimony compounds are rapidly excreted.

Recently Bartter and his colleagues<sup>1</sup> have investigated the excretion of tartar emetic in which radioactive antimony was incorporated. Antimony metal was bombarded with deuterons to produce radioactive isotopes. In this process the naturally occurring isotopes Sb<sup>121</sup> and Sb<sup>123</sup> are transformed into Sb<sup>124</sup> and Sb<sup>122</sup> respectively. The radioactive antimony was then synthesized into tartar emetic. Early work was carried out on dogs, and the authors had no reason to expect untoward results from the administration of the radioactive material to human beings. The quantity of antimony administered to one patient during 24 days was a total of 640 mg but they do not record what proportion of this was radioactive. Sb<sup>124</sup> has a half-life of 60 days, so that presumably ill effects would have shown soon. None were observed.

After a single intravenous injection the amount of antimony in the blood fell rapidly—from 0.15 mg per 100 ml immediately after injection to one-third of that amount in one hour, and to 0.01 mg per 100 ml in twelve hours.

investigations, in order, as he put it, "First, again to call the attention of workers in malaria to this promising field for investigation, secondly, to place on record Ross's claims to priority in discovery, and lastly, to vindicate myself from the charge of unscientific and unwarrantable speculation" Manson had recorded his "speculation" in the Goulstonian lectures printed in this *Journal* in 1896. This week the London School of Hygiene and Tropical Medicine, and the Ross Institute of Tropical Hygiene, celebrated the Jubilee of Ross's discovery.

### CANCER CELLS IN SPUTUM AND URINE

The increasing use of the biopsy has proved to pathologists how valuable their contribution can be to the problem of the early diagnosis of malignancy, in spite of the fact that the material submitted for examination is of necessity often very poor in quality and very small in quantity. Yet even the smallest specimens, including those taken by the needle and syringe, may yield surprisingly good results. Is it sound pathology to take a further step and consider the possibility of diagnosing malignant disease by discovering a few isolated clusters, each perhaps composed of 20 to 30 cells, in films of the sputum or urinary deposit?

The first serious attempt to answer this question was made at St Thomas's Hospital in 1935 by Dudgeon and Wrigley,<sup>1</sup> who were able to demonstrate malignant cells in the sputum in 68% of patients with proved bronchogenic carcinoma (in a series of 58 cases). Barrett<sup>2</sup> and Gower<sup>3</sup> reported positive results in 68% and 64% respectively. A very complete study was published by Wandall,<sup>4</sup> of Copenhagen, in 1944, out of 100 proved cases positive results were obtained in 84. In this series 82 of the patients were examined by bronchoscopy, it is significant that a positive diagnosis as a result of examination of biopsy specimens could be made in only 55%. By combining both methods Wandall was able to make a correct diagnosis of malignancy in 94% of proved cases. The percentage of false positives in a series of 193 sputum examinations was 3.1. Herbut and Clerf<sup>5</sup> examined the bronchial secretion removed by bronchoscope in 57 proved cases of bronchogenic cancer, and found cancer cells in 82.4%, examination of biopsy specimens gave positive results in only 42%, but a combination of both methods provided a positive diagnosis in 92.5%. It seems probable that bronchial secretion may prove to be more suitable material than sputum, it has the added advantage that if the biopsy material is a poor sample, or if for various reasons material is not removed, the growth can often be accurately localized.

The work has been carried a stage further by Woolner and McDonald<sup>6</sup> at the Mayo Clinic. They point out that negative results are to be expected in the small group of patients in whom the growth is peripheral especially if it has not opened into the airways, and also in the very large majority of cases of bronchial adenoma and cylindroma. Diagnosis from sputum examination is rather more difficult in the mucus-secreting adenocarcinoma, but is of great value in tumours arising in a large, upper-lobe bronchus out of reach of the bronchoscope.

"False positives" are recorded in from 1 to 3% of sputum examinations. A few of these were obtained in cases of chronic pulmonary infection with incomplete resolution and squamous metaplasia of the bronchial epithelium but the majority are most probably due to lack of experience with the method. The investigation must be conducted by a morbid histologist. It demands not only an intimate knowledge of the cytology of malig-

nant growths in general and of the perplexing variations in structure which are encountered in bronchial cancer, but also a period of apprenticeship in the study of the finer cytology of the sputum in non-malignant pulmonary disease and the appearances of malignant cells in film preparations made from the surface of all varieties of primary bronchial neoplasms. The specimen must be examined without delay, if this is unavoidable it should be collected in 10 ml of absolute alcohol. A minimum of five films from one specimen must be made. If clinical evidence is sufficiently in favour of neoplasm several specimens of sputum should be examined. All those who have had experience in the method agree that a positive diagnosis must rest on finding several clusters of malignant cells in the specimen. The clusters must be composed of cells which are fresh enough to show nuclear detail, so that the chromatin network and nucleoli are clearly displayed. The clusters must also be large enough for variations in nuclear shape, size, and depth of staining to be visible.

Accompanying Woolner and McDonald's paper are two others on the identification of malignant cells in urinary sediment. The first, by Daut and McDonald<sup>7</sup> records an investigation of forty consecutive cases of genito-urinary disease. In nineteen of these subsequently proved to be suffering from malignant disease carcinoma cells were found in the urinary deposit. In the second paper Ludden and McDonald<sup>8</sup> describe the appearance of malignant cells in smears of sediment from the urine of patients with malignant disease of the kidney. Neither of these papers is convincing enough to justify the routine use of the method, but both are sufficiently encouraging to stimulate further investigation.

### THE EXCRETION OF ANTIMONY

There has hitherto been little precise information about the excretion of antimony compounds which are widely used in the treatment of schistosomiasis. In this disease tartar emetic or an organic antimonial compound is injected intravenously. To be effective a course of injections, commonly on alternate days must be given. Antimony compounds differ in this respect from an arsenic compound such as neoarsphenamine, which is given once a week but resemble mapharside, which is often given daily. It is known that mapharside is much more rapidly excreted than neoarsphenamine, as is to be expected from the smaller size of its molecule. It might be assumed, therefore, that antimony compounds are rapidly excreted.

Recently Bartter and his colleagues<sup>1</sup> have investigated the excretion of tartar emetic in which radioactive antimony was incorporated. Antimony metal was bombarded with deuterons to produce radioactive isotopes. In this process the naturally occurring isotopes  $Sb^{121}$  and  $Sb^{123}$  are transformed into  $Sb^{124}$  and  $Sb^{122}$  respectively. The radioactive antimony was then synthesized into tartar emetic. Early work was carried out on dogs and the authors had no reason to expect untoward results from the administration of the radioactive material to human beings. The quantity of antimony administered to one patient during 24 days was a total of 640 mg but they do not record what proportion of this was radioactive  $Sb^{124}$  has a half-life of 60 days, so that presumably all effects would have shown soon. None were observed.

After a single intravenous injection the amount of antimony in the blood fell rapidly—from 0.15 mg per 100 ml immediately after injection to one-third of that amount in one hour, and to 0.01 mg per 100 ml in twelve hours.

Some antimony was found in the urine after 30 minutes. The drug was excreted in both the urine and faeces, in 7 days about 30% of the dose given had been excreted, and in 27 days about 70%. Four times as much was excreted in the urine as in the faeces. In the case of one patient who vomited 30 minutes after receiving the tartar emetic intravenously as much as 1.2% of the dose injected was recovered from the vomit. Presumably the tartar emetic was excreted into the stomach and produced emesis just as if it had been given by mouth. These results may be compared with those of Boyd and Roy,<sup>2</sup> who found that the total urinary excretion of sodium antimonyl tartrate during three days after intravenous injection was 4%, in the experiments of Bartter *et al.* the corresponding figure was around 16%. On the other hand, after giving a single dose of "fouadin" Goodwin and Page<sup>3</sup> found that 18-35% of the drug was excreted in 24 hours.

The results are surprising because they show that the rate of excretion of antimony, when given as tartar emetic, is less than would be expected. It cannot be said that a substance of which only 30% is excreted in seven days is rapidly excreted, and it is therefore puzzling that it is necessary to give injections at comparatively short intervals. Yet frequent injections are necessary, for the most successful clinical results are those of Alves and Blair,<sup>4</sup> who treated patients by giving three injections of sodium antimonyl tartrate on each of two successive days. One hundred patients were treated, and no viable eggs were discovered in the excreta of any of them immediately after treatment was completed, or in fifty-three patients examined three months later. Alves and Blair attempted to give antimony as an intravenous drip in the same way as mapharside, but found that it caused intense pain in the veins. In observations on the rate of excretion they also found it to be relatively slow, for at the end of three days 70-80% remained in the body.

### STRUCTURE OF VACCINIA VIRUS

A number of plant viruses have been prepared in crystalline form and the shape and size of their particles examined by electron microscopy, but considerably less has been discovered about animal viruses. The first electron micrographs to provide satisfactory evidence of structure in the vaccinia virus have now been obtained by Drs I. M. Dawson and A. S. McFarlane<sup>1</sup> at the National Institute for Medical Research, using a sufficient variety of techniques to place their main conclusions beyond reasonable doubt. Omitting details of purification, which included the confirmation of biological activity, the virus particles were in all cases "fixed" with osmic acid before examination. This is equivalent in electron microscopy to visual staining. The difference is that with the electron microscope differential scattering power depends on variations in density. The usefulness of osmic acid in particular is due primarily to the fact that osmium is one of the heaviest of the chemical elements.

For the investigation of surface structure the further method of gold-shadowing was employed. This consists in the deposition of a fine layer of gold, a few atoms thick, projected at a small angle to the surface so that a shadowing effect is produced. Particles thus prepared give an appearance which, apart from the difference in scale, is not unlike that of a lump of sugar. The surface granules are believed to represent individual macromolecules. In some cases chains of these smaller particles can be seen in the neighbourhood of the main virus particles, as if accidentally detached from them, but there is no evidence of corresponding surface scars on the main virus particles. Micro-

graphs obtained with similar osmic acid fixation or staining, but without gold-shadowing, confirm the existence of a central body, first seen in outline by Green, Anderson, and Smadel in 1942.

A further series of micrographs were obtained after treatment with minute quantities of crystalline pepsin. This is known to be a useful agent for the removal of nucleic acid from vaccinia. Its effect, as now seen in the micrographs, is to leave the central body apparently untouched while removing most or all of the material from the remainder of the virus particles, except for a presumed outer layer which resembles a membrane. The latter appears to collapse, being in general longer, narrower, and less regular in shape than in the intact particles. Further—and this is particularly well seen in micrographs of the pepsin-treated virus prepared by the gold-shadowing method—there are clear indications of folding such as would naturally be expected in a collapsed membrane. It is believed that the chains of detached macromolecules already mentioned come from this perinuclear material. On the other hand the bulk of the phosphorus and desoxyribo-nucleic acid is retained in the residue, thus appearing to be connected with the central body. To that extent, therefore, there is an indication of chemical similarity between the central body of these virus particles and a normal cell nucleus. It should be noted, however, that the virus particles are of an altogether lower order of size, and, while the term nucleus can be legitimately used in its simple physical sense to describe the observed central bodies, the cytological connotation could be misleading.

Finally, there is a suggestion based on the manner of contraction of the virus particles under different conditions of drying that there may be a supporting internal network which would permit of a concertina-like movement. What has in any case been established is that the structure of even a comparatively small animal virus is definitely more complex than that of the fully crystalline plant viruses. It also appears likely that the animal viruses can be regarded as providing a link between the bacteria, looked upon as organisms in the accepted sense, and the plant viruses, to which the term organism can scarcely be applied.

At its first meeting on June 30 the new Council unanimously elected Dr H. Guy Dain as its Chairman for the coming year. Dr Dain has been Chairman of Council since September, 1943.

At the last meeting of the "old" Council on June 28 it was decided to award to Dr John W. Bone, the retiring Treasurer, the Gold Medal of the Association. In announcing this to the Representative Body, which greeted the award with applause, the Chairman of Council said that the Association's Gold Medal was awarded to anyone "who shall have conspicuously raised the character of the profession by scientific work, by extraordinary special service, or by services rendered to the British Medical Association."

One of the first actions of the Representative Body last week was to elect as Vice-Presidents of the B.M.A. Dr Peter Macdonald, of York, and Prof R. M. F. Picken, of Cardiff. Dr Peter Macdonald has given long years of service to the Association and was from 1942 to 1945 Chairman of the Representative Body. Prof Picken, who is Provost of the Welsh School of Medicine, was outstanding as the Chairman of the Public Health Committee, and for fifteen years exerted his thoughtful influence on the Council of the Association, acting temporarily as its Chairman during the absence in India of Mr H. S. Souttar, who was Chairman at that time.

## UROLOGICAL SURGEONS IN CONFERENCE

The British Association of Urological Surgeons held a meeting in London, under the presidency of Mr Clifford Morson, from June 24 to 26. The principal subjects of discussion were the surgery of urethral stricture and the aetiology and treatment of renal and uterine calculi, but many miscellaneous papers were read and films shown, and operating sessions and demonstrations were arranged at ten London hospitals.

### Surgery of Urethral Stricture

The visitors were the guests of the Section of Urology of the Royal Society of Medicine for a discussion on the surgery of urethral stricture. It was opened by Mr H L Attwater, who referred to the slow onset of such strictures. The initial causes might be forgotten long before the stricture made itself manifest. It had been calculated that only 5% of cases appeared for treatment within five years of the initial lesion. From time immemorial man had dealt with strictures by dilatation. Attempts had been made to shorten the tedium of the process, but even to-day the melancholy conclusion must be reached that no form of treatment had yet produced a certain cure. All operations on the urethra were themselves traumatic procedures, and might be precursors of stricture, and "once a stricture always a stricture".

The first indication for surgical intervention was failure to achieve reasonable results by dilatation. The surgical measures to be employed depended largely on the particular case. The onset of urgent symptoms might call for immediate intervention, and special care was necessary if the renal function was poor. Patients with chronically distended bladders due to stricture were in much the same position as men with enlarged prostates. When surgical intervention had to be undertaken some form of deliberate approach must be adopted according to the requirements of the particular case. Operation should cause the least possible trauma to the urethra. For a long time external urethrotomy was the only approach to this problem. Internal urethrotomy had a limited application, and unfortunately far too often failed to produce a lasting result. But there were occasions when it might be useful, including those in which for some reason it was necessary to have a quick restoration of the urethra. Mr Attwater then described the various surgical procedures, including complete excision of the stricture.

Mr Terence Millin said that internal urethrotomy performed in the usual manner was a completely blind procedure, and did not fit in with the essential pathology. He described how a complete excision of the stricture was carried out, taking away as much as 6 cm of the urethra. Radical surgery had a place in treatment, especially in traumatic strictures, but it must be truly radical, and anastomosis must be obtained without tension. The results could be wellnigh permanent. He referred to one such case in which 17 operations had been done, 7 of them external urethrotomies. Then a complete excision was carried out, with an entirely satisfactory result. This result had been maintained now for six months, 11½ years after the start of the trouble. A high incidence of sexual dysfunction followed rupture of the urethra, but several of the cases on which he had operated were normal sexually, despite the loss of 6 cm of urethra.

Dr Leander (Stockholm) said that the 'pillars of wisdom' in perineal excision were (1) as complete excision as possible of all cicatricial tissue, (2) mobilization of the urethral stumps so that they could be sutured without tension, and (3) avoidance of cavities between the sutured urethra and the perineal section. He described six cases, two in boys and the others in older persons, in which these principles had been followed and a urinary stream of normal size had resulted, although in some cases more than 5 cm of urethra was removed. In one of the cases there was slight incontinence for two years, but that was the only unfavourable result.

Mr W S Mack said that he had noticed an increasing incidence of urethral stricture. Unfortunately, in the clinics, while information was available on the incidence of gonorrhoea, none was forthcoming concerning non-specific urethritis, but it was his impression that there were more cases nowadays, following the advent of sulphonamide and penicillin treatment, in which

stricture was associated with that condition. He was very much against operation for urethral stricture if it could be avoided, but in many instances operation was necessary. In spite of what Mr Millin had said, he had found certain advantages in internal urethrotomy. Mr Stewart mentioned the difficulty of treating the constricted penile urethra, and described a method of dividing the penis along the ventral surface and using the scrotal skin and foreskin in the reconstruction of the urethra.

### Renal and Vesical Calculi

Mr J M Ridley Thomas, of Norwich, gave an account of vesical calculus as found in Norfolk. He mentioned that in the first half of the eighteenth century almost every small town in Norfolk appeared to have a man skilled in lithotomy. "Stone in Norfolk" was the subject of the Address in Surgery at the Annual Meeting of the British Medical Association in 1874. But vesical calculus almost entirely disappeared between the years 1910 and 1930, the disappearance coinciding with the rising standard of living. Recognition of the importance of an adequate and balanced diet for children, and the change to mixed farming in a county which for many years was a grain-producing area had brought about this alteration. He gave certain figures relating to hospital admissions for the years 1929-38 and 1943-7. Cases of stone complicating enlarged prostate numbered 16 in the first period, 13 in the second, cases of stone following prostatectomy numbered respectively 10 and 3. Stricture of urethra, diverticuli, etc., 12 and 8, and primary stone 38 and 3. Thus in the first of these periods about 50% of calculi appeared to have no obvious underlying urinary pathology, whereas in the second period only about 10% could not be accounted for by a pre-existing lesion. Prostatic obstruction was the commonest cause of stone in older patients due in most cases to the presence of residual urine. In 1929-38, out of 76 patients 14 died, whereas in 1943-7 among 27 patients there were no deaths. Of these 27 patients, 20 were treated by lithotomy, 5 by lithotomy and 2 by other methods. For many years the lithotrite had been a popular instrument in Norfolk, but recently the number of cases suitable for its use had diminished considerably. Norfolk could no longer be considered an area where vesical calculus was common. In children it had now become very rare.

Mr L N Pyrah of Leeds, spoke on calcification of the kidney in pyloric stenosis and other conditions. He drew attention to the conditions under which calcification in the tubules of the kidney could occur. It was mainly the result of two causative factors probably operating in different degrees in different cases. The first was a local increase in the concentration of calcium ions within the kidney, brought about either by an elevation of the serum calcium, as in hyperparathyroidism, or by a reduction in the total tissue fluids of the body, as in pyloric stenosis, with vomiting and subsequent dehydration. The second factor was strong alkalinity of the reaction in the kidney tissue fluids or glomerular filtrate, either as a result of generalized alkalosis or of local changes arising from infection, in which case the concentration of calcium salts which would not otherwise be precipitated came down in the renal tubules as calcium phosphate.

In hyperparathyroidism the serum calcium was raised to values varying from 12.5 to 23 mg per 100 ml of blood. The percentage incidence of calcification for this disease was unknown, but when it occurred it was seen in the cells of the tubules in the cortical part of the kidney. Not only did calcification of the renal tubules occur in hyperparathyroidism but also calculus formation in the calices and pelvis of the kidney probably brought about by the same mechanism. Of 11 cases of hyperparathyroidism in which he had successfully removed an adenoma, 4 had renal calculi. In three of these the stones disappeared after removal of the adenoma and the administration of large quantities of fluid, together with an acidogenic diet. In hypervitaminosis D a high blood calcium was the chief operative cause in the production of renal calcification. A few cases had been reported in children of calcification in the tubules of the kidney following an overdose of cod liver oil. It was possible to study the calcification in hypervitaminosis D very readily, using the rat as an experimental animal. A moderate degree of calcification was sometimes found after only two days of an overdose of vitamin D and usually in three days. It occurred first in the tubules of the cells near

the cortex. In rats killed after four or five days of overdose a much heavier degree of calcification was found, and the calcification was less marked in the cortex and more marked in the boundary zone between the medulla and the renal cortex. Rats fed on excessive vitamin D for two or three days only and killed ten or twelve days later were usually free from calcification. It was concluded that the calcareous debris had gone into solution or had been extruded down the collecting tubules. The calcification was therefore a reversible process in its early stages. In such cases there was no evidence of any destruction of the kidney tubules or of deviation from the normal.

After illustrating the second group of conditions, in which alkalosis was the predominant factor, Mr Pyrah concluded that calcification of the tubules of the kidney occurred most commonly where there was a high serum calcium or where there was a profound alkalosis. In some cases, but not in all, it was associated with cell damage. In the early stages the calcification was a reversible process.

#### An Uncommon Bladder Condition

Mr T J D Lane, of Dublin, described an uncommon bladder condition simulating carcinoma. His interest in this subject arose out of a case which he saw in 1943, and which remained a mystery until he came across a paper by Emmett and McDonald on 'Proliferation of Glands of the Urinary Bladder simulating Malignant Neoplasm'. His case fitted in with the 'intestinal gland' variety of cystitis glandularis there described. Mr Lane went on to discuss the several possible origins of primary vesical tumours composed of glands with columnar epithelium and also of cystitis glandularis. According to the authors just mentioned there were two types of cystitis glandularis: the intestinal gland type and the subtrigonal gland type. In the former the acini were lined by a simple layer of columnar epithelium which had basically placed nuclei. These cells were filled with mucus and were indistinguishable from goblet cells of the intestinal tract. In the subtrigonal lesion the glands were lined peripherally by multiple layers of cells suggestive of stratified squamous epithelium with a single layer of columnar cells adjacent to the lumen. The mucus produced by this type was thinner, and, unlike the intestinal type, there was a tendency to cyst formation. There were no special symptoms. Painless haematuria might be present alone, or with frequency or dysuria. The whole clinical picture was confused. Biopsy was essential for proof of the presence of cystitis cystica and to differentiate it from cystitis granulosa and follicularis on the one hand and from malignant disease on the other. The resemblance to cancer in some cases had to be seen to be believed. As a rule these glandular lesions yielded to diathermy.

Although in his title Mr Lane had used the word "uncommon," he said in conclusion that the condition was probably not very uncommon. There was little doubt that, if biopsy were resorted to oftener, glandular and other forms of metaplasia would be found much more frequently.

The concluding paper at the conference was by Mr Hamilton Bailey (London) on some urological clinical entities frequently missed. Numbers of patients, he said with stone in the right ureter bore the scar of a recent appendicectomy. But we betide the patient with gangrenous appendicitis who passed blood in the urine. Until it was better known that an inflamed appendix lying in juxtaposition to the ureter could give rise to ureteritis causing haematuria lives would be lost. When blood was found in the urine the practitioner invariably ruled out appendicitis, and not infrequently the consultant aided and abetted him by treating the patient for pyelitis. When a differential diagnosis between early acute appendicitis and renal colic was at stake, urgent excretory pyelography should be undertaken. If the pyelogram showed a normal outline of the right renal calices and there was no evidence of a ureteric calculus, appendicectomy must be performed at once. Another observation by Mr Hamilton Bailey was that the reno-renal reflex, where a healthy kidney went "on strike" in sympathy with its fellow that had been subjected to operative trauma, was not a rare phenomenon. He concluded by saying that attention to the precept that a complete urinary investigation should be undertaken for every case of haematuria would result in immediate and dramatic improvement in the prognosis of tumours of the bladder.

## THE GENETICS OF CANCER

### SYMPOSIUM ON MUTATIONS AND INHERITANCE

A two-day symposium on the genetics of cancer opened in London on June 24 under the sponsorship of the Genetical Society of Great Britain and the British Empire Cancer Campaign. Some twenty papers were read, and the contributors included American, Dutch, Danish, French, and Belgian workers. The general themes were the inheritance of cancer in animals and in man and virus and carcinogen-induced mutations. The chairmen of the various sessions were Dr E B Ford, Dr A W Greenwood, Prof A Haddow, and Dr Cuthbert, Dukes.

The opening paper in the discussion on inheritance in animals was given by Dr W E Heston, of the National Cancer Institute, Maryland, who discussed the role of genes and their relationship to extra chromosomal factors in the development of mammary gland tumours in mice. He described the part played by the milk agent in transforming the normal mammary tissue cell into a malignant cell. What happened in such a transformation was still uncertain, but as the alteration was irreversible it must be a change in fundamental cell physiology. Dr Kortweg, of Amsterdam, said that the production of oestrone in female mice enhanced their susceptibility to cancer, though it could not yet be said that the production of oestrone was characteristic of high cancer strains. Susceptibility to oestrone influence was just as marked in the mammary glands of high cancer strain female mice as in those of low cancer strain.

Dr L Dmochowski, of the Department of Experimental Medicine and Cancer Research, Leeds University, spoke of three factors—the milk agent, the genetic factor, and the hormonal factor—in the origin of breast cancer in mice, and in addition other factors, such as metabolic conditions, might be concerned. The ability to transmit the milk factor to low cancer strain mice varied within very wide limits. There were really two sets of genetic factors, one controlling the susceptibility of breast tissue and the other the milk factor, which might have to be considered particularly in low cancer strain mice. In his view an increase in the hormonal factor rather than an increase in the milk factor was responsible for the development of tumours. All three factors played a part in the origin of breast cancer, and it would be imprudent, to say the least, to state which was the most important.

Prof J B S Haldane intervened, protesting that it was logically dubious to separate hormonal factors from genetic ones. It seemed to him that some genes would alter the production of hormones. If that sort of distinction were to be made the correct thing would be to distinguish between hormonal factors due to genetic agencies and, on the other hand, hormonal factors due to environment, which would include forcible breeding, castration, injection of hormones, and so on.

Dr P A Gorer, of Guy's Hospital, spoke of the significance of some studies of transplanted tumours. He said that at one time the question of transplanted tumours dominated the whole field of cancer research. To-day the pendulum had swung in the other direction, and transplants were regarded as not of much use. As a matter of fact, the studies of transplanted tumours had placed genetics "on the map" of experimental medicine. Questions of transplant compatibility were much better tackled with tumours than with normal tissues, if only for technical reasons—namely, that it was often by no means easy to see what happened to a graft of normal tissue, whereas no one could mistake a tumour. The influence of antigen II on tumour inoculation was shown in an experiment with mice. In the presence of antigen II, 28 out of 29 specimens showed a response to tumour, and with antigen II absent, out of 40 specimens 37 showed no response.

The question of virus and carcinogen mutations was presented by Dr L C Strong, of the Department of Anatomy at Yale, who gave a critical evaluation of the present status of the problem. Among other contributions to the subject Prof R D Passey, of Leeds, showed some electron microscope studies of normal and malignant tissues of high and low breast cancer strains of mice, and Dr A W Greenwood, of the Agricultural Research Council, discussed indications of the heritable nature of non-susceptibility to Rous sarcoma in fowls.

### Heredity in Human Cancer

At a later session the subject of heredity in human cancer was introduced by Prof Tage Kemp, of the Human Genetics Institute, Copenhagen. From ancient times, he said, it had been observed that cancer often occurred familiarly. The genetic aspects of the cancer problem had been the subject of extensive systematic studies in human beings during recent decades. In Copenhagen an investigation had been carried out at the Human Genetics Institute in co-operation with the Danish Cancer Registry, the Radium Centre, and numerous hospitals and clinics. Surveys of several hundreds of families picked out at random from the population had been made. So far as investigations on heredity in breast cancer and in leukaemia were concerned, these had already been published, and an investigation on cancer of the oesophagus was proceeding.

Results obtained up to now showed that tumour-causing factors might be endogenous or environmental. The chief endogenous factor was hereditary predisposition, others were somatic mutation and cytoplasmic inheritance. In the field of breast cancer the families of 197 women and 3 men were studied. According to Oluf Jacobsen, a study of these case histories gave no basis for supposing that exogenous factors played any important part in the development of breast cancer. Hereditary predisposition was indicated as the chief factor. The development of the endogenous cancers was probably due to a general hereditary predisposition, and the localization of the tumour was determined by either endogenous or exogenous factors. The general hereditary predisposition was in many pedigrees apparently inherited as a dominant character.

With regard to leukaemia, Videbaek, who had conducted this investigation, was of opinion that leukaemia as such was not inherited, it was a question of inherited predisposition to the disease. The development of leukaemia seemed to depend on various conditions—among others, on a non-specific hereditary predisposition to cancer, which was believed to be present in at least 20% of the population in general. Among the relatives of those with cancer of the body of the uterus the incidence of endogenous cancer was found to be high. In the families of those suffering from cancer of the oesophagus the disease was often found in a close male relative—father or brother. In these families, however, both the patient and the relative were often found to be suffering from chronic alcoholism, and probably it was the tendency to alcoholism and not the tendency to cancer which was inherited, the alcoholism being the cause of the oesophageal cancer.

The experiences of both clinical and experimental investigators confirmed that the probability of mammary cancer and leukaemia developing at an earlier period of life was greater when the genetic conditions were particularly favourable—that is, when there was a demonstrable hereditary taint. On the other hand the possibility of the occurrence of the disease became greater with advancing age. He concluded by saying that the supposition of somatic mutation or cytoplasmic inheritance as a cause of cancer had not been proved in human beings, the results of cytological investigations of human cancer cells were somewhat obscure.

### Family Histories of Breast Cancer Patients

Prof D Smithers, of the Royal Cancer Hospital, reported on the family histories of 459 patients suffering from cancer of the breast which had been investigated during the period 1944–7. Some attempt had been made to confirm the causes of death of relatives by letters to hospitals, doctors, and the Registrar-General's department, but such confirmation could be obtained only in a few cases. The figures, therefore, were subject to the errors of inadequate information and faulty recollection but it was believed that they were an underestimate rather than an overestimate of the incidence of cancer in the families in question. Many people died of cancer without their relations knowing the cause of death, and many patients with cancer of the breast survived for long periods following treatment and ultimately died from some other cause. Comparisons had to be made on the basis of mortality, no adequate morbidity statistics were available, so that it was not possible to include in the figures patients living who had or had not had cancer for comparison with the expected incidence in the general population.

Of the 459 families analysed, the patient in 292 of the cases had no knowledge of a family history of cancer. Of the 167 cases in which the patient reported cancer in the family, 76 mentioned cancer of the breast. In 54 of the cases a history of cancer in more than one member of the family was obtained. The 167 patients with a known family history of cancer stated that they knew of this on their mother's side only in 88, on their father's side only in 34, among brothers and sisters in 33 and on both paternal and maternal sides in 12. This gave a maternal side history of 100 cases, compared with a paternal side history in 46. Of the 459 mothers, 30 were known to have died of cancer, but none had had cancer of the breast. The patients had 1,008 sisters, 288 of whom had died, 59 in infancy and another 200 of causes believed to have been other than cancer. Of the 29 known to have died of cancer, 11 had had cancer of the breast, 11 sisters living had also received treatment for breast cancer. Of the 1,059 brothers, 425 had died, 75 in infancy, and another 332 of causes other than cancer. Eighteen had died of cancer, but none of cancer of the breast. One was alive following treatment for cancer.

Analysing these figures, he was unable to confirm the finding of Jacobsen that the age of onset of the disease was lower in those who had a history of cancer in the family, in fact, the age was higher in the cancer family group, though not significantly so. The average age at diagnosis with no history of cancer was 54, and with a cancer history 55.3, though for those with a history of cancer of the breast in the family the figure was 54.1. It was to be expected that patients giving a family history of cancer at the time of diagnosis would tend to have a higher average age than the remainder, because the brothers and sisters of the younger patients were less likely to have reached the cancer age than those of the older subjects. Patients reporting cancer in brothers and sisters were in fact found to be in the older age groups in the series, as compared with those reporting cancer in fathers, mothers, uncles and aunts. The average age of those reporting cancer in brothers and sisters was 59.7 and of those reporting cancer in mothers and fathers 54.6—a significant difference. Those reporting older generation cancer were of an age close to those reporting no cancer history (54).

This information suggested that there was a significantly high death rate from cancer of the breast in the families of patients with that disease, but no higher death rate from other forms of cancer than would be expected in the general population.

Prof Smithers concluded by giving the details of three families taken from the group that he had been discussing. In one case the maternal grandmother of the patient died of carcinoma of the breast. She had five sons and three daughters. All three daughters developed cancer of the breast, the age of onset being between 60 and 65. One of the sons died of carcinoma of the rectum. The eldest of the sisters was the patient's mother. The patient herself developed carcinoma of the breast at the age of 42. One of the other sisters had no children, the other had a son and daughter, neither of whom up to date had developed cancer. The brother with cancer of the rectum had three daughters and three sons, and all three daughters had carcinoma of the breast, the age of onset being between 40 and 50.

### Genetic Study of Mammary Cancer

The final contribution to the symposium was by Prof L S Penrose, of the Galton Laboratory. The study of mammary cancer, he said, formed a most advantageous starting-point for the investigation of the hereditary factors in cancer, because it was more easily recognized and more accurately diagnosed than malignant growths at most other sites. Moreover it produced in the great majority of patients a clearly defined range of pathological conditions, which included spheroidal-celled carcinoma, Paget's disease of the nipple, adenocarcinoma, and the typical scirrhous condition in long-standing cases.

It was still doubtful whether heredity played any significant part aetiotogically. To try to resolve this uncertainty most investigators in recent years had collected a series of cases, noted the incidence of similar disease among their relatives and compared it with the corresponding incidence among a control group of cases free from the disease and selected at random. But the difficulties in obtaining a satisfactory control group of family histories had been demonstrated repeatedly. Many

workers still considered that there was not enough evidence to prove the reality of familial transmission of mammary cancer or any type of human malignant disease.

A survey which Prof Penrose proceeded to describe had been undertaken in an endeavour to remove some of these uncertainties. The material collected began in each instance with a patient attending a clinic after the diagnosis of mammary cancer had been made. The patients were all personally interviewed and hospital records and reports were searched. Altogether 521 histories of cases of mammary cancer were collected. Eleven were set aside as doubtful, and 510 were analysed from different points of view. The mean age at onset was 51.7 years, with a standard deviation of 11.4 years. In 116 pedigrees one or more relatives with mammary cancer were ascertained. The distribution of these 116 familial cases and the mean age of onset (51) were similar to those of the remaining non-familial cases. Of the 510 women 408 were married and 91 of these had no children, the infertility ratio significantly exceeded the value for married women of the same mean age given by the Registrar General in 1938, and supported the view that nulliparity was an aetiological factor.

Prof Penrose discussed various points arising from this investigation and quoted many statistics. Only his conclusions can be given. The evidence from the mothers, sisters, fathers, and brothers strongly suggested that transmission of a specific factor was a major cause of mammary cancer. The hypothesis of inheritance of special organic disposition suggested by Bauer was supported by the homolateral familial findings. The theory, however, implied a significant decrease in the incidence of malignancy of other types in these families, which was not found in Prof Penrose's survey, nor was there any increase in the incidence of cancer generally which might have suggested a general hereditary predisposition to malignancy of any type. The familial incidence of mammary cancer among siblings was not high enough to suggest any Mendelian explanation of its inheritance. The consanguinity test for rare recessive genes gave negative results.

In view of the work of Bittner on mice, a factor derived from maternal cytoplasm, transmitted by milk, colostrum, or by the cytoplasm of the ovum, might be a specific cause. If that were so, maternal relatives should be more frequently affected with mammary cancer than the corresponding paternal relatives. In his series, among maternal aunts there were 29 mammary against 21 other cases of malignant disease, whereas among paternal aunts there were only 16 mammary cases, against 24 of other types. Those figures were suggestive, but not conclusive, evidence of maternal line inheritance. They derived some slight support from the investigation of maternal and paternal grandparents, where a relative excess of mammary cancer among maternal grandmothers was noted. In both the parental and grandparental generations sisters were more often affected than mothers so far as breast cancer was concerned—a fact of some genetical importance. A search for evidence that mammary cancer could be inherited through maternal milk gave entirely negative results, but a more accurately planned study with that point specially in mind might show a different picture.

In closing the meeting Dr E. B. Ford from the chair said that the symposium had shown the study of cancer to be very much more an integral part of the study of biology than he had supposed, and this ought to be taken into account in the general work of the biologist. The genetics of cancer must be considered in the whole field of cancer research work at every level. The general practitioner often felt that genetics had very little to offer him as a guide to his own work, but such researches as Prof Smithers had been carrying out at the Royal Cancer Hospital showed that a family history of cancer might help in diagnosis, it might indicate the possibility of cancer being the source of certain symptoms shown by a patient, and it might in that way lead to an early diagnosis of the disease.

St Thomas's Hospital has now issued the first post-war edition (1948) of the *Alphabetical and Local List of Old Students*. The names and addresses of old students are listed as well as names of the past and present honorary staff, hospital staff, and winners of scholarships and medals. Owing to the high cost of production the book can no longer be distributed free, but copies are obtainable at the cost of 2s. 6d. from the School Beadle.

## BRITISH HOSPITALS ASSOCIATION

### ANNUAL MEETING

The annual meeting of the British Hospitals Association was held in London on June 25, with Sir Bernard Docker presiding. In a telegram expressing regret at his inability to attend, the Duke of Gloucester said that he believed that the voluntary spirit still had a great part to play and that the hospitals would be able to count upon its exercise in the future.

Sir Bernard Docker said that in the development of the voluntary hospitals was enshrined the whole history of the progress of medicine. From two hospitals in the twelfth century their numbers had increased to over 1,100 providing 100,000 beds. Their work had not been limited to caring for the sick; pioneering discoveries in preventive medicine had their origin in the hospitals and their laboratories. The hospitals had been animated by a spirit of service, by independence, and by a continual striving for further improvement. They had set standards which were striven after all over the world. In the last half-century they had treated some 35 million in-patients. The number of out-patient attendances was equal to the population of this country five times over.

Mr R. L. Newell paid a tribute to the Association for the help it had given to the British Medical Association in the very difficult negotiations of recent times. Up and down the country meetings of hospital boards had in his opinion been needlessly funereal about what they should, on the contrary, regard as the finest hour of voluntary effort. At long last the public had become convinced of their duty to maintain the hospital service which would no longer be dependent on charitable bequests. He had been gratified to observe in the various regions how many people wished to serve on hospital boards. He was not one of those who thought that hospitals were best run by medical men. The knowledge and understanding of people of all ranks and professions were needed, so that the new hospitals freed from the menace of insolvency and the stigma of charity might become the prototype for the world to copy. Some of the British Hospitals Association's activities might become redundant, but it would be a great tragedy were the Association to disappear. It might lead to bureaucratic control of hospitals which they all feared. Let voluntary effort, as exemplified in the Association, uphold at all costs the spirit of initiative and humanity which had for so long been the mainstay of voluntary hospitals.

Mr Arnold Walker, chairman of the Central Midwives Board, hoped that in the new National Health Service the lessons of the past would not be ignored. Dealing with the midwives' position, he remarked on the misfortune that, while 1,000 new midwives were needed every year to make up the establishment, less than half of those who qualified with the Board became practising midwives. This and other problems had recently been investigated by a Working Party whose report would soon appear. In the future just as many midwives would be needed as in the past, and they must be highly qualified. It was therefore essential that the training schools, with their long traditions, should be preserved intact and developed to the greatest possible extent. Mr Walker gave statistics showing the high proportion of practising midwives trained by voluntary hospitals. The midwife herself was complementary to the doctor so far as normal cases were concerned, her statutory right to take charge of such cases must be preserved if the present standards of the profession were to be maintained. They would disappear entirely were she reduced to the level of a maternity nurse.

Sir George Aylwen, treasurer of St Bartholomew's, speaking of management and administration, expressed the conviction that the voluntary spirit would be maintained by those who had agreed to serve on hospital management committees and he stressed the importance of guarding against regimentation in the control and administration of the new hospital service. The meeting was also addressed by Miss M. M. Edwards, secretary of the Nursing Recruitment Centre, and Mr J. P. Wetenhall, secretary of the Association. Later the business meeting was held, at which the speakers were Sir George Martin and Sir Bertram Ford, president of the Contributory Schemes Association.

# ONE HUNDRED AND SIXTEENTH ANNUAL MEETING of the British Medical Association

HELD AT CAMBRIDGE, JUNE, 1948

## THE SECTIONS SUMMARY OF PROCEEDINGS

*In subsequent issues there will be printed in the BRITISH MEDICAL JOURNAL a few of the opening papers read at the Scientific Sections. All the papers will be published in full in a separate volume of Proceedings. The reports of the discussions in this and successive issues are intended to give members who were not present a general idea of the proceedings.*

### SECTION OF MEDICINE

Wednesday June 30

#### Thiouracil in Thyrotoxicosis

With the president, Dr Leslie B Cole (Cambridge), in the chair Prof H P Himsworth (London) opened a discussion on the use of thiouracil in the treatment of thyrotoxicosis. Prof Himsworth's paper is printed elsewhere in this issue (p 61).

Mr Charles Donald (London) stressed the variability of the disease, functional symptoms difficult to assess were often added. He thought it was impossible to differentiate between diffuse and adenomatous goitres. The drawback to thiouracil was that it produced a damping down rather than a complete cure of the condition, patients often thought they were cured, but after thyroidectomy discovered that this had not been the case. The period of treatment by thiouracil was always being increased, and natural remission was not common in this disease. A complication of treatment with thiouracil which was not often mentioned was thrombosis. The results of surgery were quick, and the mortality in good hands was as low as 1%. The patient was soon able to return to full work and relapse was uncommon.

Dr D Verel (Aberdeen) described 61 cases under treatment with thiouracil for six months to three and a half years. Of these cases 9 had had auricular fibrillation, which could be treated first with quinidine and then thiouracil. There had been 8 cases of neutropenia, with no deaths. This should not occur if the dangers were explained to the patient and the drug stopped. There were 3 pregnancies in this series, one infant was born with a goitre, but in the other two cases the drug had been stopped before the thirtieth week and in one iodine was substituted. Koilonychia occurred in 7 cases, and while the anaemia did not respond to thiouracil the nail changes improved.

Dr L W Hale (Camborne) said that in Cornwall, an endemic goitre area, their experience was preponderantly of secondary thyrotoxicosis. Thiouracil complications had been mild and occasioned minimal interference with medical treatment, but he had yet to be reassured about the prognosis of fully developed agranulocytosis. In his cases tachycardia and fibrillation had been the most difficult features to control. Remission of symptoms following thiouracil was transient, and he felt that the emotional tone of the thiouracil-controlled patient was often not wholly satisfactory. Specialist surgical treatment might give better results than thiouracil but the latter was preferable to surgery which was in any way short of that standard.

Dr Russell Fraser (London) thought it important to consider the problems of the technique of thiouracil treatment. The greatest risk was that of goitrogenesis rather than toxicity.

He described patients who on large doses had developed a large goitre, eye signs, diplopia, and thiouracil-resistance. He thought, therefore, that it was necessary to get quickly on to the maintenance dose.

Dr H Cookson (Bournemouth) described 120 cases, many over the age of 50 treated with methyl thiouracil. He thought the drug was good in young patients with a smooth diffuse goitre and in old patients who were poor risks for surgery. In the large intermediate group surgery was the better treatment after premedication with the drug.

Dr L C Martin (Cambridge) said that thiouracil had two clear advantages. First, in the preparation of patients for operation, particularly those with rheumatic heart disease, it widened the time over which the operation could be safely performed. Secondly, in exophthalmic ophthalmoplegia it happened often that surgery made the patient worse. If thiouracil did this, it was known that surgery was contra-indicated.

Dr J N Milnes (Ipswich) gave an account of 60 cases and thought the drug was good as a pre-operative measure, but dangerous if the patient was not under personal observation.

The president thought the kernel of the problem was how far thiouracil would prevent thyrotoxic heart disease. In this he had come to the conclusion that it was not as good as surgery.

### SECTION OF SURGERY

Wednesday, June 30

#### Tuberculous Adenitis

With the president, Mr Vernon C Pennell (Cambridge) in the chair, Mr Denis Browne (London) opened a discussion on tuberculous adenitis restricting his remarks to cervical lymph-nodes. Among the portals of entry to the 'culture media' at the upper end of the respiratory tract he regarded the adenoids as especially important, and had found tuberculosis present in 3 out of 15 groups of adenoids removed at operation. Differentiation between tuberculous and streptococcal cervical lymphadenitis depended upon observation of the course of the disease. Tuberculous lymph nodes grew progressively over a period to reach a more or less final size at which necrosis occurred, while in streptococcal adenitis the lymph nodes waxed and waned in size from time to time, finally recovering without necrosis. In mixed infections the nodes behaved in a rather varied way. Calcification occurred only in tuberculous lymph-nodes.

The treatment of streptococcal lymphadenitis was expectant until suppuration occurred, when pus was expelled by gentle pressure through an incision in a skin fold which was left open but not drained. In the treatment of tuberculous adenitis Mr Browne had found no advantage in x rays, sea air, general measures ultra-violet light, splinting, and aspiration. Incision and curettage was inaccurate but occasionally effective. Excision and suture was disappointing for several reasons. It was not in fact, as had sometimes been claimed, finally curative. It left a scar, it flattened the neck, it injured important structures, including nerves, it was dangerous, and it could not be combined with tonsillectomy. Incision and forcible digital expression was regarded as the treatment of choice, applicable as soon as pus had formed and when the skin had just become adherent. Digital expression was repeated some twelve or fifteen times until only pure blood was expressed. The resultant wound was fomented and tonsillectomy was performed.

Mr Hugh Reid (Liverpool) was concerned chiefly with tuberculous adenitis in sites other than the neck. Tuberculous mediastinal lymph-nodes were often responsible for bronchitis, atelectasis, pneumonia, and in childhood even bronchiectasis. He regarded human sputum as the infecting agent in mediastinal as in pulmonary tuberculosis and believed a Ghon focus in the lung to be the portal of entry.

Mr Ronald Reid (Colchester) reviewed 300 personal cases of tuberculous cervical adenitis treated in an Essex sanatorium and followed for an average period of three years. The upper deep cervical group of glands were affected in 196 of 223 successive cases, the nodes in the posterior triangle in 23, and the supraclavicular nodes in 4. The tonsils, adenoids, and

affected nodes were together believed to constitute a Ghon focus which showed three clinical stages: activity with matting, subsidence with discrete mobility, and resolution with fibrosis and calcification. The patient was treated by sanatorium measures for an average period of sixteen weeks and the tonsils were then removed and any caseous glands were dissected out, soft and gelatinous lymph-nodes were not interfered with. After this management, and a post-operative convalescence of three weeks on the average, 298 patients remained in good general health for 2 months to 8 years (average 3 years). A recurrence at the old site developed in 11 patients. The cosmetic result was regarded as good in 276 bad in 11, and indifferent in 15. Two patients subsequently suffered from pulmonary and one from meningeal tuberculosis.

Mr R R M Porter (Southport) agreed with Mr Browne that the results of gland excision were unsatisfactory. He covered the gland out gently with a spoon. Mr K Watson (Redhill) questioned whether a lymph-node could be squeezed out completely by digital pressure; he sometimes found a deep gland still present at subsequent dissection. Mr J Scholefield (Isleworth) suggested that the popularity of ultra-violet radiation in these cases was due to the difficulty of finding sanatorium accommodation.

Mr A S Till (Oxford) inquired whether Mr Browne's method gave a more permanent result than excision. Mr F E Stock (Liverpool) expressed satisfaction with the results of radical excision, performed even in the presence of an abscess. Mr A Duff (Salisbury) said that a combination of sharp spoon and discretion had all the advantages, and greater certainty, than Mr Browne's squeezing method. Mr W M Dennison (Glasgow) reported that a method not dissimilar to Mr Browne's had been used in Glasgow for many years, with the addition of curettage for the extraction of deeply placed lymph-nodes. Excision of skin, glands, and fascia after the method of Mr Hamilton Bailey had been employed with advantage in the same city for upwards of twenty-five years in late disease with wide skin-involvement.

Mr Denis Browne replied briefly to the discussion.

## SECTION OF OBSTETRICS AND GYNAECOLOGY

*Wednesday June 30*

### The Problem of Infertility

With the president Dr J R Campbell Canney (Cambridge) in the chair, Dr Bethel Solomons (Dublin) opened a discussion on the problem of infertility and its treatment. He said that he regarded sterility and impaired fertility as synonymous terms, and he suggested that fertility tests should be done on prospective mates. Sex education should be given in schools and by parents and the married couple desirous of having children should obtain advice about sex in general from the gynaecologist. Dr Solomons considered a marriage as sterile if there was no pregnancy after two years. He thought that male infertility was responsible for this in about 50% of cases. In the woman anatomical abnormalities should be corrected. While the cervical mucus might be an important factor in sterility, various operations on the cervix did not prevent a woman conceiving. A plea was made for the recording of fatalities due to tubal insufflation, and three such cases were described. However, the method was so useful that it should still be carried out: the use of opaque fluids in diagnosis and treatment was advocated. No fatality had resulted from their injection in a large series of cases. The results of operations on the Fallopian tubes were disappointing: about 10% success being all that could be achieved. Hormone therapy was discussed. Finally the use of contraceptives by the newly wed couple was deprecated. Donor insemination was discussed and condemned.

Mr Albert Sharman (Glasgow) reviewed the literature on fatalities following tubal insufflation, and described experimental work on rabbits. While there were many records of deaths due to the use of air or oxygen, there was so far no record of a death when carbon dioxide had been employed. Taking one minute to inject air into a rabbit's vein, death ensued after the injection of 3 ml, in the case of oxygen, death occurred after 4 ml, and when carbon dioxide was used, after

15 ml or more. Physiologists had stated that the occurrence of embolism due to carbon dioxide was almost impossible because of its rapid absorption. Mr Sharman said that he had now done about 3000 cases at the Royal Samaritan Hospital, Glasgow, and there had been no death as a result of tubal insufflation with carbon dioxide. There had been three cases of pelvic infection, two of which were severe but not fatal.

Mr Kenneth Walker (London) devoted his remarks to a consideration of the means by which the sperms were transported to the ovum. He stressed that the husband was almost entirely responsible for the success or failure of the sperms to reach their goal. The three important factors were ejaculation, motility of the sperms, and penetration, or the condition of the cervical plug. It should never be assumed that ejaculation was satisfactory until careful inquiries had been made. Faults in the ejaculatory phase of coitus, though much less apparent, were almost as frequent as faults in the preceding phases. Ejaculatio praecox was not of great importance in considering childlessness. Absence of ejaculation was much more important, and had not received the attention it merited; it occurred, for example, in the man of low sexuality who suffered from latent homosexuality, fetichism, sadism, and so on. These cases required prolonged skilled psychotherapy, which even so was not always successful. Another type of male did have an orgasm but did not produce semen, probably because of neuromuscular imbalance, as semen was often found in the urine passed after the act. Mr Walker was of the opinion that oligozoospermia was due to variation in the testicular contribution to the total bulk of the semen. He pointed out that a sheath specimen and a post-coital specimen from the same man might vary considerably. The post-coital test had not been given the prominence its value entitled it to receive. The quality of the sperms was of more importance than their number.

Mr Percy Malpas (Liverpool) said that recurrent abortion was due to a multiplicity of causes, but that in some cases there was clearly a recurrent factor whose nature was unknown. He suggested that in the absence of any discernible disease to account for these cases a reasonable hypothesis would be that they were due to a recurrent failure of the nervous mechanism whereby uterine quiescence was maintained. In this connexion the lightness of the attachment of the placenta to the uterine wall in the early months of pregnancy was emphasized and the evidence in favour of this hypothesis was discussed. Emotional shocks were the most common cause of spontaneous abortion in healthy pregnancy. The analogous behaviour of other hollow pelvic viscera was described, and attention was drawn to the oxytocic effect of various purgatives. It was also important that the rate of growth of the uterus should be equal to the rate of growth of the ovum, otherwise "missed" abortion occurred.

Mr Cecil Binney (Barrister-at-Law, The Temple) said it was plain that the law could not ignore artificial insemination. Artificial insemination *per se* was not a crime and it did not constitute adultery which was important with regard to the law of divorce. The branch of law in which artificial insemination introduced most problems was that concerned with the inheritance of property. Usually it would be necessary for the child to forgo any inheritance. The only solution for this impasse was the abolition of all settled funds. The law of nullity was untouched by artificial insemination. It was most important that any doctor performing this operation should have the written consent of husband and wife.

There was a lengthy discussion to which Dr Bethel Solomons replied. He said that carbon dioxide was the gas of choice for insufflation of the tubes. He was interested in the fact that Mr Sharman had found it safe to insufflate in the premenstrual phase when insufflation could be combined with biopsy of the endometrium. He said that in recurrent abortion, in addition to the drugs usually used, he had prescribed, from the time when he was an assistant antisyphilitic remedies in non-syphilitic cases. He wondered how Mr Malpas could "keep the nervous mechanism quiet." Methods such as the adoption of babies which had psychological effects were important. To keep a patient in bed for months to prevent a miscarriage was not always practicable. Dr Solomons concluded by pointing out that there was no greater proportion of abnormal babies in cured sterility cases than in ordinary pregnancies.

## SECTION OF ANAESTHETICS

Wednesday, June 30

## Anaesthesia for Chest Surgery

The president, Dr Z. Mennell (London) was in the chair and opened the proceedings by pointing out that this was the first meeting of the Section of Anaesthetics since 1933. He was pleased to find that the British Medical Association no longer regarded anaesthesia as a branch of pharmacology.

Dr John Millar (Newcastle upon Tyne) began the discussion on anaesthesia in chest surgery. She stressed that new methods of anaesthesia, resuscitation and teamwork were largely responsible for the progress in thoracic surgery. The anaesthetist must be a good bronchoscopist and must have a practical knowledge and experience of the special problems. The actual agent used was of less importance. Careful pre-operative preparation and assessment of the respiratory and cardiac function of patients were necessary and for this purpose differential spirometric recordings were occasionally of value. She advocated local analgesia for endoscopies, drainage of empyema and lung abscesses and in the surgery of pulmonary tuberculosis. In thoracoplasties it was advisable to examine the patient radiologically on the day of operation to detect any unsuspected spread of the disease. After premedication with amorphon and scopolamine brachial plexus and paravertebral nerve blocks were performed and the subscapular region infiltrated. A unilateral vagal block at the base of the skull was useful in extra-fascial apicectomy to ensure freedom from persistent coughing. In the subsequent stages of thoracoplasty the anaesthetist might have to be helped out by light chloroform anaesthesia. For lung resections general anaesthesia was advised. The wet case was best controlled by bronchial intubation. Endo-bronchial anaesthesia was less certain and more difficult. The respiration must be controlled or assisted to prevent paradoxical movement and mediastinal flap. While the use of curare offered many advantages there was always a danger of residual post-operative weakness and reduced tidal exchange which predisposed to post-operative collapse. The anaesthetic methods for operations on the oesophagus, heart and great vessels were described. During heart surgery cardiac irregularities had been controlled by the application of procaine to the epicardium or by the intravenous injection of 2 ml of 2% procaine. The necessity for the complete restoration of normal respiratory physiology at the close of every operation was stressed; there must be no hesitation in performing a bronchoscopic aspiration if necessary. Post-operative x-ray examinations were important to detect the presence of a pneumothorax or of atelectasis. Finally it was most important to replace blood as it was lost during the operation and not to wait until a large transfusion had to be given. In the elderly a sudden large transfusion might result in pulmonary oedema.

Dr E. H. Rink (London) followed with a short paper based on his experience of the surgical treatment of 50 cases of congenital pulmonary stenosis. There had been 8 immediate deaths, 3 at the time of operation and 5 within six hours of the operation. One child had died since leaving hospital and 4 cases had been inoperable. Post-operative complications such as atelectasis and pleural effusion were common. The pre-operative condition of these children was poor. They were very cyanotic, and had intense clubbing of the fingers and no exercise tolerance. They were undersized and had no resistance to infection, so that it was often necessary to operate in the presence of respiratory infection. Despite all this they tolerated anaesthesia and operative trauma well. The operation might last five or more hours and no matter how bad the child's condition, hope must not be abandoned until the child was dead. Premedication was by means of oral "nembutal" or rectal thiopentone. A slow induction with cyclopropane or a little ether was followed by the instillation of a few drops of methocaine over the back of the tongue and the insertion of a cuffed endotracheal tube. A plain tube with a pack could be used. Anaesthesia was maintained with cyclopropane or ether, controlled respiration being employed throughout; curare had proved of great value in this respect. The dangerous periods were when the pleura was opened, when the pulmonary artery

was clamped to make the anastomosis and after the anastomosis had been completed when the circulation had some difficulty in adjusting to the new conditions. The excellent result of the operation more than justified it. Dr Rink then described the operation of valvulotomy, for which he had anaesthetized four cases with one post-operative death. Adrenaline was the best resuscitant in all these cases.

A lengthy discussion followed in which Dr G. S. W. Orme (London) stated that he regarded local anaesthesia for thoracoplasty as an interesting exercise for the anaesthetist rather than as a procedure with advantages over general anaesthesia. He used a mixture of methocaine 1:2000 with procaine 1:100 and 1:300,000 adrenaline, but even 1:5000 methocaine worked well. He had never seen bronchial intubation or endobronchial anaesthesia performed without trauma and for this reason preferred the other methods, which were preferable. He did not think that post-operative atelectasis was related to spill over and considered that there might be some reflex contraction of the lung. Dr P. I. Wolmer (Bristol) stressed the importance of always having a curare charged and procaine ready to treat cardiac irregularities.

Dr T. Cecil Gray (Liverpool) said that he did not agree that Dr Millar had given any cogent evidence that local analgesia was to be preferred to general anaesthesia in thoracoplasty. It was not a valid argument to say that the cough reflex was maintained during the operation for curare to be effective there must be a fixed effect which was not the case during thoracoplasty. Curare appeared to be under suspicion but it enabled the anaesthetist to be carried out under a very light anaesthesia which was a definite advantage at the end of the operation. In heart surgery and for cyclopropane anaesthesia the anaesthetist was seen to be often if curare was used because deep anaesthesia was required. Under modern conditions post-operative pulmonary oedema probably had little to do with the anaesthesia but it did occur about the fourth day after operation and was frequently associated with an oedema of the pleural membrane.

Dr H. H. Pinkerton (Glasgow) also supported the use of general anaesthesia for thoracoplasty as it was the only method of the scapula and ensured freedom from any spinal spread of the periosteal stripping. In view of these facts before an operation too much significance must not be attached to the vital capacity. Thoracoplasty had been successful in cases in which the vital capacity had been as low as 500 c.c.m. provided that the physiotherapists had reported that the patients had good control of their respiration. His experience with white bloods had been unfortunate as his three cases had been desperate risks and had ended fatally.

Dr Edith Gilchrist (London) questioned the advisability of intubating tuberculous patients and Dr J. G. Bourne (London) wondered whether the cardiac upset that occasionally followed vagal block might not be due to the adrenaline which would be in the injected local anaesthetic although he did not consider that there had been an intravascular injection in the cases which he had seen. The president wound up the discussion with a query about the method of sterilization of solutions of morphine given intravenously.

In reply Dr John Millar again stressed the arguments in favour of local analgesia for thoracoplasty. The cough was perfectly effective during the operation if the apex of the lung was supported by the surgeon. Answering a question about the best mode of anaesthesia for the repair of congenital tracheo-oesophageal fistulae she considered that it was important for the anaesthetist to keep an eye on the investigations from the beginning. She had seen a great deal of trouble in these cases due to the passage of barium into the air passages. Lipiodol was a better opaque medium. She preferred local anaesthesia and a posterior approach to the mediastinum which did not entail opening the pleural cavity. Oxygen was given under pressure a small blood transfusion was also needed. Dr Rink, replying to Dr G. F. Randon Smith (Liverpool) considered that death must be assumed if there was no response to cardiac massage within five minutes. Irreversible cerebral changes consequent upon a period of anoxia must be remembered.

### Abdominal Relaxation

With Dr C H Budd (Cambridge), *vice president*, in the chair Dr C B Lewis (London) read a short paper on abdominal relaxation. He defined abdominal relaxation as the attainment of complete muscular flaccidity, complete peritoneal flaccidity, minimal respiratory movements, and contracted viscera. Relaxation was essential in abdominal surgery and was made difficult because the tone of the accessory muscles of respiration persisted even after other muscles had become relaxed, and because the posterior fascial sheaths of the abdominal muscles were adherent to the peritoneum. Further, respiratory movements still caused embarrassing movements of the viscera. Dr Lewis reviewed the main agents and combinations commonly used to achieve abdominal relaxation, and said that spinal analgesia fulfilled perfectly all the desiderata. Contrary to expectations, curare had not replaced other methods, and he described the technique of induction of anaesthesia with thiopentone followed by the intrathecal injection of heavy nupercaine. Endotracheal intubation was performed, and general anaesthesia maintained with a further small dose of thiopentone and it necessary nitrous oxide or cyclopropane. He had experience of 100 cases in which gastrectomy was performed under this method of anaesthesia. Headaches were rare following it, and in the unconscious patient marked falls in blood pressure did not occur. He limited his initial dose of ephedrine to 3/4 gr (50 mg) and emphasized that the results of spinal analgesia depended not on the drug used but on the particular technique and the maintenance of full oxygenation. Ether, although safe was being infrequently used because of the disturbed convalescence which followed and cyclopropane alone gave poor relaxation. Curare he considered a great advance, but it was too easy to give, and once it had been given the anaesthetist had lost control. He considered its use to be contraindicated in heavily built patients when the Trendelenburg position was to be employed. Intubation was a most valuable aid to relaxation, as it ensured a completely free airway. Such accessory aids as flexion of the patient's knees should not be overlooked.

In the discussion which followed, Dr Agnes J Gray (Preston) considered that the supplementary agents alone used by Dr Lewis were sufficient for abdominal surgery without a spinal analgesia, especially if curare was used. Dr R F Woolmer (Bristol) deprecated the custom of supporting the patient in the Trendelenburg position only by the knees. Compression of the calves predisposed to post-operative thrombosis, and also in that position the pelvis was tilted at an angle, putting the rectus abdominis muscle on the stretch and making the attainment of adequate relaxation almost impossible. Dr B Williams (Middlesbrough) said that as a gynaecologist he was interested both in relaxation and in the posture of the patient. He deprecated the use of shoulder rests. He had had a case of brachial plexus palsy, a complication made more likely by the modern tendency for the anaesthetist to keep an arm available for intravenous injections. He had found bromethol a useful basal narcotic and felt it facilitated subsequent relaxation.

Dr H R Youngman (Cambridge) had used 'mivanesin' with some success especially in anal operations, when stretching of the anus produced deep respiration but did not result in any troublesome reflex laryngeal responses. It might be that the solvent at present employed for this substance contraindicated its use. Dr R W Cope (London) stressed the dangers of tragic sequelae following spinal analgesia with heavy damages being awarded later against the hospital surgeon, and anaesthetist. For these reasons he had turned to curare with thankfulness. Dr R Jarman (London) had experience of spinal analgesia in 18 000 cases, and said that the late Dr Sebrechts, of Bruges had employed it in no fewer than 30 000 cases. It would be folly to condemn such a useful method too lightly. The results were invariably better when an endotracheal tube was passed

### Caudal Extradural Block

Dr G C Steel (London) said that caudal extradural block had been employed for assessing the outcome of sympathectomy in cases of hypertension. 'Metycaine' 1-2% was used and the segmental level of the resulting analgesia checked against the fall in blood pressure. This method gave a more accurate forecast of the likely results of operation than the usual tests

including high spinal analgesia, which caused complete loss of muscle tone and consequently impaired the venous return.

Paravertebral lumbar sympathetic block gave good results in the treatment of phlegmasia alba dolens, but so did caudal block. Sympathetic vasoconstrictor impulses caused spasm of the arterioles and venules in this condition, and the caudal block released this spasm and restored the normal fluid exchange. This method had also been applied successfully in the treatment of a case of glomerulonephritis with hypertension and pulmonary oedema and in cases of anuria. Convulsions in cases of eclampsia could be controlled in this way but it was essential that the patient should be closely observed for any circulatory collapse which might be dangerous in this condition. Caudal analgesia was a useful alternative to spinal block in surgery and had been tried in many pelvic operations. It was especially useful in vaginal hysterectomy because of the good perineal relaxation and relatively avascular field. He recommended it, too, for analgesia for the termination of pregnancy in cases of pulmonary tuberculosis. Finally, as a nerve block for the relief of the pain of pelvic carcinoma it had proved of great value. In these cases 40 to 60 ml of 'proctoecaine' was usually given although to obtain complete relief intrathecal injections of alcohol might be required.

Dr A R Hunter (Manchester) pointed out that the results of sepsis following sacral block were as disastrous as the meningo myelitis which might follow intrathecal injections, and Dr H J Brennan (Manchester) stated that collapse was not uncommon after caudal anaesthesia. Dr T Cecil Gray (Liverpool) objected to the procedure because of its complete unpredictability. The block often went too high resulting in a severe fall in blood pressure and collapse of the patient.

### Intubation in Infants

This meeting of the Section ended with a short discussion opened by Dr R W Cope (London), on 'When to intubate in babies and children'. After reviewing the anatomy of the infantile larynx and stressing the deep anaesthesia required for intubation, he warned against the possibility of passing the endotracheal tube into the right main bronchus. The criticism that the thickness of the tube diminished the air entry did not seem valid except when it was obstructed by drops of mucus. Trauma with subsequent laryngeal oedema was a very real danger. He considered that babies and children should be intubated (a) in the treatment of asphyxia neonatorum and for any surgical operations on the newborn (b) for abdominal operations such as those performed for congenital pyloric stenosis, duodenal atresia or intussusception during the first few weeks of life and (c) for operations during the first months of life for cleft lip and cleft palate. In the latter cases a tube made of a coiled spring was safest and most certain.

A discussion followed in the course of which Dr R F Woolmer (Bristol) asked whether topical analgesia of the larynx was advisable in children, and whether the apparatus described by Humby and Hawksley was still in use for cleft palate. Dr Agnes J Gray (Preston) advocated the preliminary swabbing of throats to detect the presence of streptococci and urged the usefulness of intubation by touch in the newborn, not every maternity department had a laryngoscope ready. Dr G S W Organe (Westminster) questioned the wisdom of intubating babies more often than was absolutely necessary and deprecated the use of an endotracheal tube to maintain the airway when other methods would suffice. Dr J N Fell (Colchester) urged the value of endotracheal intubation for tonsillectomy in children, pointing out that this was the only method by which a patient could be kept lightly anaesthetized for this operation.

Dr R W Cope in reply, felt that careful positioning of the patient for tonsillectomy was a better solution than intubation. As the latter procedure would have to be performed nasally it might cause bleeding and create difficulties when the adenoids had to be removed subsequently. He had urged intubation during anaesthesia for Ramstedt's operation because this might not be a short procedure, and the presence of a tube allowed the anaesthesia to be lightened from time to time. He did not use topical analgesia in children because of the danger of toxic reactions, and did not consider that Humby and Hawksley's device was safe, not infrequently the metal parts were of the wrong curvature and the rubber tube became detached from them.

## SECTION OF DISEASES OF THE CHEST

Wednesday, June 30

## Bronchial Carcinoma

After Dr R R Trail (London) the president had welcomed the speakers Mr R C Brock (London) opened the discussion on bronchial carcinoma. He said that the place of surgery in the treatment of bronchial carcinoma was now established. There was no need to argue it, it had placed bronchial carcinoma among curable diseases. It was still a terrible disease and operation was possible in a few cases only. It was therefore very important that diagnosis should be made early and patients be referred for prompt treatment. Although the ultimate act of treatment was in the surgeon's hand the case rests on the ability and the best chance of saving life lay in the hands of earlier medical attendants. They must therefore consider early manifestations.

As in all diagnosis of malignant disease the most important thing was to think of it. Any departure from normality in a patient of cancer age should suggest it. The leading symptom was cough, there were also pain, haemoptysis and loss of infection. The average duration of the disease was six months, therefore it was no good waiting three to four months making a diagnosis. Radiography was of the first importance including x-ray examination of a barium swallow, bronchoscopy, next.

The cases that he had seen (1941-7) numbered 66. 75 (11) of these were operable. Earlier series (1933) had shown 8 of 224 cases. There had been steady improvement each year, thus the 1947 operability rate was 21. That improvement was due partly to increased skill in removal but chiefly to earlier diagnosis.

The total number of patients operated on was 96 of whom 18 had died from the operation, 78 had survived. Twenty-eight had died since 50 were still alive—the longest period of survival being nine years, 8 had survived over five years.

There was still room for improvement and some of this would come from a more complete operation. For example the latest natural development was blood dissection pneumonectomy. The greatest need was still early diagnosis and early reference for skilled investigation. In that matter the general practitioner and the consultant physician were of greater importance.

Mr G A Mason (Newcastle upon Tyne) emphasized the large amount of work done of the lung entitled for thoracic surgical clinics. His clinic had dealt with nearly 1,000 cases in the last 15 years. He found that there was likely to be as much as five months' delay in submitting the patient to treatment after the patient had seen a doctor. Cases were still held as 'suspicious' when investigation rather than observation was required.

'Delayed resolution' and 'unresolved pneumonia' should be regarded as carcinoma until proved otherwise. In pneumonia was certainly not a contraindication to pneumonectomy nor was a blood stained effusion. The operability figure was now about 20%. Out of 202 cases of pneumonectomy there were 9 surviving 4 years, 2 surviving 5 years, 2 surviving 6 years and 1 surviving 7 years.

Mr Mason advised x-ray therapy for all undifferentiated growths whether operated upon or not for those with malignant glands found at operation and for growths in those who declined operation, those unsuited for it and those found inoperable on exploration.

Mrs E L G Hilton (London) said that in analysis had been made of the inoperable cases of cancer of the bronchus seen at University College Hospital, London during the years 1940-6 inclusive to assess the benefit received by those patients who had had x-ray treatment. Three hundred and sixty cases of cancer of the bronchus had been seen. Of these 147 had been too ill, and the disease had been too advanced to receive irradiation treatment. Only 89 had been considered suitable for a radical course of x-ray treatment. The remaining 114 receiving only palliative irradiation. Ten cases received post-operative treatment after pneumonectomy.

The speaker emphasized the following factors influencing the selection of suitable cases for a radical course of x-ray treatment: the general condition of the patient, the extent of the growth, the presence of sepsis, of tuberculosis in association

with cancer or of an effusion. She mentioned the importance of ascertaining whether the full effect of the first course of treatment had taken place before treating the second course and stressed the difficulty of differentiating between partial response changes in lung tissue and recurrent growth. Planning the use of irradiation was facilitated by following a regular series of roentgenoscopic examination.

The average duration of life of the patient who was treated by x-ray treatment was between 9 and 10 years. Of patients who had received palliative x-ray treatment 5 had died, 10 patients who had had a radical course of x-ray treatment had died 15 months. The duration of life of 10 patients who had received a radical course of x-ray treatment and who were alive on June 1948 was 10 years. The results obtained from x-ray treatment in the treatment of cancer suggested that good palliative treatment could be obtained and in some cases life could be prolonged for a long period.

Dr R K Trail stressed the importance of the early diagnosis of bronchial carcinoma. He said that the early diagnosis of bronchial carcinoma was the key to the successful treatment of the disease. He said that the early diagnosis of bronchial carcinoma was the key to the successful treatment of the disease. He said that the early diagnosis of bronchial carcinoma was the key to the successful treatment of the disease.

Dr L H Yeo, the director of the Chest Clinic, said that the early diagnosis of bronchial carcinoma was the key to the successful treatment of the disease. He said that the early diagnosis of bronchial carcinoma was the key to the successful treatment of the disease. He said that the early diagnosis of bronchial carcinoma was the key to the successful treatment of the disease.

Mr Brock said that the early diagnosis of bronchial carcinoma was the key to the successful treatment of the disease. He said that the early diagnosis of bronchial carcinoma was the key to the successful treatment of the disease. He said that the early diagnosis of bronchial carcinoma was the key to the successful treatment of the disease.

## Surgery of Congenital Heart Disease

Dr J M H Campbell (London) opened the discussion on congenital heart disease. He said that in cases of congenital heart disease the early diagnosis was of great importance. He said that in cases of congenital heart disease the early diagnosis was of great importance. He said that in cases of congenital heart disease the early diagnosis was of great importance.

In cases of congenital heart disease the early diagnosis was of great importance. He said that in cases of congenital heart disease the early diagnosis was of great importance. He said that in cases of congenital heart disease the early diagnosis was of great importance.

With cases of congenital heart disease the early diagnosis was of great importance. He said that in cases of congenital heart disease the early diagnosis was of great importance. He said that in cases of congenital heart disease the early diagnosis was of great importance.

The usual operation was an end to side subclavian pulmonary anastomosis on the side *opposite* to the aortic arch. In successful cases the results were excellent, and a patient who could do nothing might quickly walk a mile or more and remain a normal colour, except on an especially cold day or after heavier exertion. In his series of patients rather less than one sixth had died, and in one sixth an anastomosis had not been found possible or the improvement was only slight to moderate. In two thirds of the patients the results had been extremely good, and except for a little increase in the size of the heart in most of them there seemed to be no drawback to the artificial patent ductus. A direct attack had been made on the pulmonary valve by Mr Brock, and this operation held out considerable hope.

Mr T Holmes Sellors (London) believed that the uncomplicated case of patent ductus arteriosus was a surgical matter. The danger of infective endocarditis was very real, and heart failure was certainly not unknown. Marked relief was obtained on removal of the turbulence. Cardiac invalidism was a condition to be deplored. In children under 5 their small size and the occasional spontaneous closure of the ductus contraindicated operation. Healthy and symptom-free adults might reasonably elect to await events. If any cyanosis was present the ductus should probably not be occluded. The results of ligature or division of the ductus were highly satisfactory. One death in 71 cases had occurred. Many of the so-called recanalizations were probably instances of an additional cardiac lesion. With one exception he had used a simple ligature with non-absorbable material in the form of a Ballance saily-knot.

The indications for surgery in cases of coarctation of the aorta were still being evolved. He had advised operation only where the symptoms of hypertension, such as headache and dizziness, had been really marked.

In cases of pulmonary stenosis the results of the operation evolved by Taussig and Blalock were excellent in a number of patients. At the very least it provided some years of more than tolerable life. The Potts operation was appealing. Both Holmes Sellors and Brock had described an operation for stenosis in the pulmonary valve.

In the discussion Mr R C Brock said that he believed there was a large measure of agreement between physician and surgeon that cases of patent ductus should be operated upon. In coarctation of the aorta more information was needed about the indications for operation. The results of the Blalock operation had been good. It was difficult to reconcile closing a patent ductus in one type of case and making a patent ductus in another type of case. Valvulotomy might have possibilities. Dr A Rae Gilchrist (Edinburgh) said that 7 years was the optimum age for operation on patent ductus or on coarctation of the aorta with symptoms.

Mr G A Mason said that the risk of recanalization must be small if the patent ductus was adequately ligated. Tape seemed rather uncertain. He used four double ligatures of linen thread, size 20. He had had no recurrences, although his series was small because of his reluctance to do the operation in uncomplicated cases. His own preference in cases of pulmonary stenosis was for the Potts type of operation, the aortic pulmonary anastomosis being much simpler than the Blalock operation.

## SECTION OF ORTHOPAEDICS

Wednesday June 30

### Lesions of the Intervertebral Disk

With the president, Professor T P McMurray (Liverpool), in the chair, an introductory paper by Prof Norman M Dott on the neurosurgical aspects of intervertebral disk lesions was read by Mr G L Alexander (Edinburgh). One of the penalties of modern civilized life was man's liability to develop spinal weaknesses, one of the most important of which was the protrusion of intervertebral disk substances. Although this took place commonly in front and at the sides of the vertebral bodies, it was chiefly important as a crippling problem when occurring posteriorly into the spinal canal or vertebral foraminae. The incidence of such lesions was considered to be approximately 300 new cases per million population per annum, insurance statistics

tended to show that this was a conservative estimate. In the aetiology the sudden assumption of violent activity either in the form of military training or athletic pursuit in people of otherwise sedentary habit seemed to be of particular significance. The importance of a national "keep-fit policy" in youth was very great. Local trauma, particularly under conditions of surprise, was perhaps the most common story. Trauma of all kinds was of significance in at least half of the cases studied. Males were involved twice as often as females, in whom pregnancy increased the liability to such lesions, and the age incidence was chiefly between 20 and 50, though the youngest patient operated upon was 15 and the oldest 72. The commonest syndrome was the association of lumbago and sciatica with a history of remissions, paraesthesiae and paresis. Lumbago or sciatica might be found alone. Scoliosis was common and particularly a tendency to assume a pronograde stoop. In half of the cases radiological narrowing of the disk was found, and in a similar proportion there was a significant rise in the protein content of the cerebrospinal fluid. Bilateral syndromes might be produced by a single disk protrusion or by a double lesion of the same disk or by single lesions of two disks. In some cases multiple disk lesions were discovered. The protrusion might be so marked and so affect the cauda equina that the case might become a surgical emergency. Skeletal peculiarities of congenital origin sometimes caused difficulty in localization but otherwise were not of significance in relation to treatment. There were a variety of pathologically different protrusions of nuclear substance. Some formed only a small lateral nodule, others dissected relatively far from the disk, others were seen as necrotic masses which penetrated the dura and produced a considerable granulation-tissue reaction. Yet others might escape detection in the posture most usual for operative exposures.

At operation precise haemostasis was necessary, complete removal of all nuclear tissue was performed aided by special gouges and nibblers copied respectively from those used by the dental surgeon and the otolaryngologist. In disk lesions associated with spondylolisthesis the loose neural arch was removed, the prominent edge of the lower vertebra smoothed off, and after the disk had been removed bone chips were put in its place and tibial grafts inserted posteriorly.

In diagnosis the particular conditions to be differentiated were various forms of epiduritis, tuberculosis involving the disk, primary radiculitis, and conditions simulating disk protrusion, nuclear granulomas, and other tumours. Diagnosis localizing the affected disk was correct in 93% of cases, errors were generally due to the presence of multiple protrusions and second interventions were necessary in 2% of cases. At Edinburgh they were prejudiced against the use of opaque myelography, but now that innocuous materials were again available it was an open question.

Operative results showed no mortality and 85% of the patients were fit for their former or equivalent jobs. Fusion operations were not necessary. Forceful manipulation was dangerous and epidural injection did not help. The chief question posed was that of the part which rest should play in conservative treatment.

Mr Norman Capener (Exeter) emphasized the importance of lesions of the intervertebral disks other than posterior protrusion. The assumption that practically every patient suffering from lumbago and sciatica was "a disk lesion" was dangerous. There were no unmistakable signs clinically or radiologically of posterior protrusions. Disk protrusions were associated with underlying physical and psychological defects and caused local disturbances and, sometimes more important, a widespread physiological disintegration—all of which indicated the overwhelming need for thoroughly efficient conservative treatment. In advocating the use of the plaster jacket for achieving physiological control, reinforced where necessary by traction upon the pelvis in recumbency, the speaker stated that not only was it the best method for all three elements of the problem but it also enabled the separation of the group likely to require operation. Operation should rarely be required. Statistics were given which showed that, if such treatment and an efficient programme of after care were applied early, the end-results were at least as good as those in some published groups of cases in which operative treatment had been practically the only method of approach.

Mr R H Young (London) who had had experience of 791 laminectomies done before August 1947, relied upon the history

of backache or sciatica or both, this was recurrent, with complete freedom from pain between attacks. With such a history, if forward bending was restricted and sideways bending free, if straight-leg raising was limited and radiological examination negative for other conditions, then the patient had a disk lesion. In the first attack rest in bed in the position of greatest comfort was advised. In the less severe cases the patients would get better whatever was done so long as physiotherapy was avoided. In operative treatment he performed a complete laminectomy with exploration of the last two lumbar disks. Protrusions at both levels were found in 12% of cases.

Col D. McVicker (Belfast) felt that manipulative treatment which was not forcible had an important place in early treatment. A great deal could be done without anaesthesia and without hurting the patient to relieve spasm. Many men could be got back to work within a few days. Surely this was better than doing nothing for two months and then operating.

Dr Rowland Hill (London) discussing brachial neuritis, in which nowadays mechanical lesions of the cervical intervertebral disks were considered important, said that the pendulum had swung too far from the infective factors and that in sciatic pain also they would do well to keep in mind such infective factors whatever mechanical lesion might also be present.

Mr A. L. Eyre-Brook (Bristol), although favouring conservative treatment, did not believe that it should be persisted in too long. If after four weeks in a typical case relief was not forthcoming, operation should be undertaken. Mr J. Hardman (Sheffield), while appreciating the importance of conservative treatment, thought that it was not fair to compare results with those of neurosurgical operations, which were usually performed for cases in which orthopaedic treatment had failed. Nevertheless out of 200 cases operated upon and studied by an independent observer two-thirds were improved though half of the cases operated on had some persistent weakness or aching in the back. This latter point was also noted by Mr H. H. Langston (Southampton). He made a plea for the use of epidural saline injections for recurrent attacks not of severe degree. This technique probably relieved by separating adhesions between the nerve roots and the protrusion.

Mr N. Ross Smith (Bournemouth) mentioned the urgent need for impartial investigation and the publication of results of operative treatment. He felt much more caution should be exercised in assessing results. More attention should be devoted to other lesions of disks. In all these cases the problem was not one primarily of operation but of the adjustment of posture and physical activity, of physical retraining and occasionally of mechanical support. Major A. Hale, discussing the results of operation in the Army, said that the duration of symptoms made no difference to the results, and that while these were satisfactory in that 80% of patients were back at full work within a year, only 3% were completely free of all symptoms. Mr B. Whitchurch Howell (London) believed that the younger the patient and the greater the pain the sooner should laminectomy be performed, the reverse applied to the older patient.

Mr Bryan McFarland (Liverpool) agreed that intensity of pain was the important criterion but thought that a large proportion of cases were cured by conservative treatment. The president, Professor McMurray, said he had been startled by the briefness of the clinical examination which Mr Young had thought suitable. He mentioned a number of conditions which might be overlooked. He believed manipulative treatment should play an important part in treatment, for many of these problems were in fact due to back strain.

### Injection Treatment of Osteoarthritis

Mr Grant Waugh (Sunderland) showed a film of his lactic-acid injection treatment, details of which have already been published. The treatment was based upon the observation of alteration in pH which occurred in the haematoma associated with fractures which at a certain stage of healing became relatively acid. In rheumatoid arthritis the joint fluids became relatively alkaline (pH 7.8) and in osteoarthritis more so (pH 8). Injections were given weekly or fortnightly and varied in amount from 1 ml in an interphalangeal joint to 2-4 ml in the wrist and shoulder, 5-10 ml in the knee and 10-15 ml in the hip joint. Before injection the joints were aspirated and afterwards

manipulation and frequent active exercises were carried out by the patient. The results in osteoarthritis and in the less active forms of rheumatoid arthritis were most encouraging in the greater mobility achieved and in the relief of pain. A group of patients with bilateral joint lesions had been treated on one side by injection and physical therapy and on the other side by physical therapy alone. The relief on the side injected was such as to cause the patients to clamour for similar treatment on the other side. Radiographic control had shown that, in the speaker's experience, if the lateral approach was used the difficulty of getting the injection into the hip joint had not been great.

## SECTION OF PATHOLOGY AND BACTERIOLOGY

Wednesday June 30

### The Rhesus Factor

With the president, Professor H. R. Dean (Cambridge), in the chair Professor D. F. Cappell (Glasgow) opened a discussion on the recent advances in our knowledge of the Rh factor. He surveyed the pioneer work in this field and paid tribute to the original work done by the Cambridge workers in the president's department. He pointed out that the haemolytic diseases of the newborn which resulted from the iso-immunization of an Rh-negative mother were increased enormously when she had been additionally immunized by an incompatible Rh blood transfusion. The dangers of such a transfusion to women of child-bearing age could not be too strongly stressed. Pregnancy heterospecific in the ABO groups rarely caused haemolytic disease, and in fact the iso-immunization of Rh-negative mothers in heterospecific ABO pregnancy was significantly less than when mother and child belonged to the same ABO group. Prof. Cappell then discussed the difference between complete and incomplete antibodies and disagreed with the suggestion that icterus gravis was caused only by the complete antibody. After reviewing the terminology he went on to show that anti-C and anti-D sera reacted differently in large surveys and there had now been demonstrated variants  $C^w$ ,  $C^u$ , and  $C^v$ , D and  $D^u$ , which could not be separated. Several case histories of families with homozygous and heterozygous fathers were described, including one in which the 18th child was the first affected. He refuted the suggestion that Rh incompatibility could cause mental deficiency apart from kernicterus or diffuse cortical staining.

Dr P. L. Mollison (London) stressed the importance of the direct Coombs' test in the diagnosis of haemolytic disease of the newborn, supplemented by accurate serial estimations of haemoglobin, bilirubin estimations, and examinations of a blood film for the degree of erythroblastæmia. Most cases showed a correlated degree of anaemia, hyperbilirubinaemia and erythroblastæmia in the cord blood. He regarded 3 mg of bilirubin per 100 ml as the borderline of abnormality, and showed that most cases had more than 10 nucleated RBC per 100 leucocytes. If the blood was examined a few hours after birth the findings were altered by the rise in haemoglobin values that occurred in all infants who were allowed to recover their placental blood and by the rise in bilirubin concentration which always took place in the neonatal period. Haemolytic disease caused death at four stages: (1) *in utero* at any time after the 24th week of pregnancy; (2) at delivery or within 12 hours of it (They were both associated with severe anaemia and death from cardiac failure occurred); (3) 2-4 days after birth—then infants had involvement of the central nervous system and were deeply jaundiced; (4) 7-14 days after birth—these were more frequently the result of poor production rather than excessive blood destruction. Dr Mollison then described the technique of exchange transfusion after premature termination of pregnancy, which he called the most rational treatment for this disease. The proportion of Rh-positive cells remaining at the end of the transfusion depended on the infant's initial red cell count and the amount of blood exchanged. 400 ml usually sufficed for a 90% exchange if the donor blood had at least 5 million RBC per  $cu\ mm$ . He had an overall mortality on this procedure of 28% with kernicterus in only 6% of the survivors. As methods and prognosis varied so much no comparison of results was yet possible.

Dr R. R. A. Coombs (Cambridge) then described an investigation of haemolytic disease in newborn foals. He had

The usual operation was an end to-side subclavian pulmonary anastomosis on the side *opposite* to the aortic arch. In successful cases the results were excellent and a patient who could do nothing might quickly walk a mile or more and remain a normal colour except on an especially cold day or after heavier exertion. In his series of patients rather less than one-sixth had died, and in one-sixth an anastomosis had not been found possible or the improvement was only slight to moderate. In two thirds of the patients the results had been extremely good, and, except for a little increase in the size of the heart in most of them, there seemed to be no drawback to the artificial patent ductus. A direct attack had been made on the pulmonary valve by Mr Brock, and this operation held out considerable hope.

Mr T Holmes Sellors (London) believed that the uncomplicated case of patent ductus arteriosus was a surgical matter. The danger of infective endocarditis was very real, and heart failure was certainly not unknown. Marked relief was obtained on removal of the turbulence. Cardiac invalidism was a condition to be deplored. In children under 5 their small size and the occasional spontaneous closure of the ductus contraindicated operation. Healthy and symptom-free adults might reasonably elect to await events. If any cyanosis was present the ductus should probably not be occluded. The results of ligation or division of the ductus were highly satisfactory. One death in 71 cases had occurred. Many of the so-called recanalizations were probably instances of an additional cardiac lesion. With one exception he had used a simple ligation with non-absorbable material in the form of a Ballance staly-knot.

The indications for surgery in cases of coarctation of the aorta were still being evolved. He had advised operation only where the symptoms of hypertension, such as headache and dizziness, had been really marked.

In cases of pulmonary stenosis the results of the operation evolved by Taussig and Blalock were excellent in a number of patients. At the very least it provided some years of more than tolerable life. The Potts operation was appealing. Both Holmes Sellors and Brock had described an operation for stenosis in the pulmonary valve.

In the discussion Mr R C Brock said that he believed there was a large measure of agreement between physician and surgeon that cases of patent ductus should be operated upon. In coarctation of the aorta more information was needed about the indications for operation. The results of the Blalock operation had been good. It was difficult to reconcile closing a patent ductus in one type of case and making a patent ductus in another type of case. Valvulotomy might have possibilities. Dr A Rae Gilchrist (Edinburgh) said that 7 years was the optimum age for operation on patent ductus or on coarctation of the aorta with symptoms.

Mr G A Mason said that the risk of recanalization must be small if the patent ductus was adequately ligated. Tape seemed rather uncertain. He used four double ligatures of linen thread, size 20. He had had no recurrences, although his series was small because of his reluctance to do the operation in uncomplicated cases. His own preference in cases of pulmonary stenosis was for the Potts type of operation, the aortic pulmonary anastomosis being much simpler than the Blalock operation.

### Lesions of the Intervertebral Disk

With the president, Professor T P McMurray (Liverpool), in the chair, an introductory paper by Prof Norman M Dott on the neurosurgical aspects of intervertebral disk lesions was read by Mr G L Alexander (Edinburgh). One of the penalties of modern civilized life was man's liability to develop spinal weaknesses, one of the most important of which was the protrusion of intervertebral disk substances. Although this took place commonly in front and at the sides of the vertebral bodies, it was chiefly important as a crippling problem when occurring posteriorly into the spinal canal or vertebral foraminae. The incidence of such lesions was considered to be approximately 300 new cases per million population per annum, insurance statistics

tended to show that this was a conservative estimate. In the aetiology the sudden assumption of violent activity either in the form of military training or athletic pursuit in people of otherwise sedentary habit seemed to be of particular significance. The importance of a national "keep fit policy" in youth was very great. Local trauma, particularly under conditions of surprise, was perhaps the most common story. Trauma of all kinds was of significance in at least half of the cases studied. Males were involved twice as often as females, in whom pregnancy increased the liability to such lesions, and the age incidence was chiefly between 20 and 50, though the youngest patient operated upon was 15 and the oldest 72. The commonest syndrome was the association of lumbago and sciatica with a history of remissions, paraesthesiae, and paresis. Lumbago or sciatica might be found alone. Scoliosis was common and particularly a tendency to assume a pronograde stoop. In half of the cases radiological narrowing of the disk was found, and in a similar proportion there was a significant rise in the protein content of the cerebrospinal fluid. Bilateral syndromes might be produced by a single disk protrusion or by a double lesion of the same disk or by single lesions of two disks. In some cases multiple disk lesions were discovered. The protrusion might be so marked and so affect the cauda equina that the case might become a surgical emergency. Skeletal peculiarities of congenital origin sometimes caused difficulty in localization but otherwise were not of significance in relation to treatment. There were a variety of pathologically different protrusions of nuclear substance. Some formed only a small lateral nodule, others dissected relatively far from the disk, others were seen as necrotic masses which penetrated the dura and produced a considerable granulation-tissue reaction. Yet others might escape detection in the posture most usual for operative exposures.

At operation precise haemostasis was necessary, complete removal of all nuclear tissue was performed aided by special gouges and nibblers copied respectively from those used by the dental surgeon and the otolaryngologist. In disk lesions associated with spondylolisthesis the loose neural arch was removed, the prominent edge of the lower vertebra smoothed off, and after the disk had been removed bone chips were put in its place and tibial grafts inserted posteriorly.

In diagnosis the particular conditions to be differentiated were various forms of epiduritis, tuberculosis involving the disk, primary radiculitis, and conditions simulating disk protrusion, nuclear granulomas, and other tumours. Diagnosis localizing the affected disk was correct in 93% of cases, errors were generally due to the presence of multiple protrusions and second interventions were necessary in 2% of cases. At Edinburgh they were prejudiced against the use of opaque myelography, but now that innocuous materials were again available it was an open question.

Operative results showed no mortality and 85% of the patients were fit for their former or equivalent jobs. Fusion operations were not necessary. Forceful manipulation was dangerous and epidural injection did not help. The chief question posed was that of the part which rest should play in conservative treatment.

Mr Norman Capener (Exeter) emphasized the importance of lesions of the intervertebral disks other than posterior protrusion. The assumption that practically every patient suffering from lumbago and sciatica was "a disk lesion" was dangerous. There were no unmistakable signs clinically or radiologically of posterior protrusions. Disk protrusions were associated with underlying physical and psychological defects and caused local disturbances and, sometimes more important, a widespread physiological disintegration—all of which indicated the overwhelming need for thoroughly efficient conservative treatment. In advocating the use of the plaster jacket for achieving physiological control, reinforced where necessary by traction upon the pelvis in recumbency, the speaker stated that not only was it the best method for all three elements of the problem but it also enabled the separation of the group likely to require operation. Operation should rarely be required. Statistics were given which showed that, if such treatment and an efficient programme of after care were applied early, the end-results were at least as good as those in some published groups of cases in which operative treatment had been practically the only method of approach.

Mr R H Young (London) who had had experience of 791 laminectomies done before August 1947 relied upon the history

of backache or sciatica or both, this was recurrent, with complete freedom from pain between attacks. With such a history, if forward bending was restricted and sideways bending free, if straight-leg raising was limited and radiological examination negative for other conditions, then the patient had a disk lesion. In the first attack rest in bed in the position of greatest comfort was advised. In the less severe cases the patients would get better whatever was done so long as physiotherapy was avoided. In operative treatment he performed a complete laminectomy with exploration of the last two lumbar disks. Protrusions at both levels were found in 12% of cases.

Col D McVicker (Belfast) felt that manipulative treatment which was not forcible had an important place in early treatment. A great deal could be done without anaesthesia and without hurting the patient to relieve spasm. Many men could be got back to work within a few days. Surely this was better than doing nothing for two months and then operating.

Dr Rowland Hill (London) discussing brachial neuritis, in which nowadays mechanical lesions of the cervical intervertebral disks were considered important, said that the pendulum had swung too far from the infective factors and that in sciatic pain also they would do well to keep in mind such infective factors whatever mechanical lesion might also be present.

Mr A L Eyre-Brook (Bristol), although favouring conservative treatment, did not believe that it should be persisted in too long. If after four weeks in a typical case relief was not forthcoming, operation should be undertaken. Mr J Hardman (Sheffield), while appreciating the importance of conservative treatment, thought that it was not fair to compare results with those of neurosurgical operations, which were usually performed for cases in which orthopaedic treatment had failed. Nevertheless out of 200 cases operated upon and studied by an independent observer two-thirds were improved though half of the cases operated on had some persistent weakness or aching in the back. This latter point was also noted by Mr H H Langston (Southampton). He made a plea for the use of epidural saline injections for recurrent attacks not of severe degree. This technique probably relieved by separating adhesions between the nerve roots and the protrusion.

Mr N Ross Smith (Bournemouth) mentioned the urgent need for impartial investigation and the publication of results of operative treatment. He felt much more caution should be exercised in assessing results. More attention should be devoted to other lesions of disks. In all these cases the problem was not one primarily of operation but of the adjustment of posture and physical activity of physical retraining and occasionally of mechanical support. Major A Hale, discussing the results of operation in the Army, said that the duration of symptoms made no difference to the results, and that while these were satisfactory in that 80% of patients were back at full work within a year, only 3% were completely free of all symptoms. Mr B Whitchurch Howell (London) believed that the younger the patient and the greater the pain the sooner should laminectomy be performed, the reverse applied to the older patient.

Mr Bryan McFarland (Liverpool) agreed that intensity of pain was the important criterion but thought that a large proportion of cases were cured by conservative treatment. The president, Professor McMurray, said he had been startled by the briefness of the clinical examination which Mr Young had thought suitable. He mentioned a number of conditions which might be overlooked. He believed manipulative treatment should play an important part in treatment, for many of these problems were in fact due to back strain.

#### Injection Treatment of Osteoarthritis

Mr Grant Waugh (Sunderland) showed a film of his lactic-acid injection treatment, details of which have already been published. The treatment was based upon the observation of alteration in pH which occurred in the haematomata associated with fractures which at a certain stage of healing became relatively acid. In rheumatoid arthritis the joint fluids became relatively alkaline (pH 7.8) and in osteoarthritis more so (pH 8). Injections were given weekly or fortnightly and varied in amount from 1 ml in an interphalangeal joint to 2-4 ml in the wrist and shoulder, 5-10 ml in the knee, and 10-15 ml in the hip joint. Before injection the joints were aspirated and afterwards

manipulation and frequent active exercises were carried out by the patient. The results in osteoarthritis and in the less active forms of rheumatoid arthritis were most encouraging in the greater mobility achieved and in the relief of pain. A group of patients with bilateral joint lesions had been treated on one side by injection and physical therapy and on the other side by physical therapy alone. The relief on the side injected was such as to cause the patients to clamour for similar treatment on the other side. Radiographic control had shown that, in the speaker's experience, if the lateral approach was used the difficulty of getting the injection into the hip joint had not been great.

## SECTION OF PATHOLOGY AND BACTERIOLOGY

Wednesday June 30

### The Rhesus Factor

With the president, Professor H R Dean (Cambridge), in the chair Professor D F Cappell (Glasgow) opened a discussion on the recent advances in our knowledge of the Rh factor. He surveyed the pioneer work in this field and paid tribute to the original work done by the Cambridge workers in the president's department. He pointed out that the haemolytic diseases of the newborn which resulted from the iso-immunization of an Rh-negative mother were increased enormously when she had been additionally immunized by an incompatible Rh blood transfusion. The dangers of such a transfusion to women of child-bearing age could not be too strongly stressed. Pregnancy heterospecific in the ABO groups rarely caused haemolytic disease, and in fact the iso-immunization of Rh-negative mothers in heterospecific ABO pregnancy was significantly less than when mother and child belonged to the same ABO group. Prof Cappell then discussed the difference between complete and incomplete antibodies and disagreed with the suggestion that icterus gravis was caused only by the complete antibody. After reviewing the terminology he went on to show that anti-C and anti-D sera reacted differently in large surveys and there had now been demonstrated variants  $C^w$ ,  $C^u$ , and  $C^v$ . D and  $D^u$ , which could not be separated. Several case histories of families with homozygous and heterozygous fathers were described, including one in which the 18th child was the first affected. He refuted the suggestion that Rh incompatibility could cause mental deficiency apart from kernicterus or diffuse cortical staining.

Dr P L Mollison (London) stressed the importance of the direct Coombs' test in the diagnosis of haemolytic disease of the newborn, supplemented by accurate serial estimations of haemoglobin, bilirubin estimations, and examinations of a blood film for the degree of erythroblastæmia. Most cases showed a correlated degree of anaemia, hyperbilirubinaemia and erythroblastæmia in the cord blood. He regarded 3 mg of bilirubin per 100 ml as the borderline of abnormality, and showed that most cases had more than 10 nucleated RBC per 100 leucocytes. If the blood was examined a few hours after birth the findings were altered by the rise in haemoglobin values that occurred in all infants who were allowed to recover their placental blood and by the rise in bilirubin concentration which always took place in the neonatal period. Haemolytic disease caused death at four stages: (1) *in utero* at any time after the 24th week of pregnancy, (2) at delivery or within 12 hours of it. (They were both associated with severe anaemia and death from cardiac failure occurred), (3) 2-4 days after birth—then infants had involvement of the central nervous system and were deeply jaundiced, (4) 7-14 days after birth—these were more frequently the result of poor production rather than excessive blood destruction. Dr Mollison then described the technique of exchange transfusion after premature termination of pregnancy, which he called the most rational treatment for this disease. The proportion of Rh-positive cells remaining at the end of the transfusion depended on the infant's initial red cell count and the amount of blood exchanged. 400 ml usually sufficed for a 90% exchange if the donor blood had at least 5 million RBC per cumm. He had an overall mortality on this procedure of 28% with kernicterus in only 6% of the survivors. As methods and prognosis varied so much no comparison of results was yet possible.

Dr R R A Coombs (Cambridge) then described an investigation of haemolytic disease in newborn foals. He had

investigated six cases in which the symptoms were absent at birth with progressive lethargy, weakness, pallor, and haemoglobinuria. This latter was the first sign in the severe cases. Because of lack of knowledge of blood groups of horses and grouping sera the use of compatible blood in treatment was very difficult. In testing for antibody his direct antiglobulin sensitivity test using rabbit anti-horse-globulin serum was positive in all the cases and negative in all the controls. All the animals affected showed profound anaemia, no erythroblasts were found in any of the cases, and there was no reticulocyte count higher than 0.04%. Histologically there was no evidence of extramedullary erythropoiesis, and this was attributed to the long gestation period of 11 months. His colleague, Dr Herd (Cambridge), had attempted to produce the picture of haemolytic disease of the newborn in rabbits experimentally and had encouraging results.

#### Occasional Papers

With Professor W. G. Barnard (Vice President) in the chair Dr A. B. Bratton (London) discussed the histological findings in the thymuses of 70 cases of myasthenia gravis. These had been removed at operation and had considerably influenced the course of the disease in the majority. Comparison with controls of similar age groups showed that the weight and shape of the gland were the same and did not support the theory of persistence of the gland in myasthenia. There was however, a qualitative difference in that the myasthenic thymuses showed denser concentrations of lymphocytes in the islets with a small number of lymphocytes in the medulla and a structure resembling a germ centre in the cortical nodules. These were present in 66 of the myasthenic glands and in only 3 of non-myasthenic control glands, suggesting that the thymus was reacting rather like lymphoid tissue than like epithelial tissue. Tumours were present in 13 out of 70 cases of myasthenia gravis and these showed a varied picture with different amounts of small cells resembling lymphocytes and large pale foamy cells which were probably epithelial. The tumours could be called lympho-epithelioma of the thymus, and occasionally metastasized.

Dr M. H. Gleeson White (Cambridge) described four cases of *H. influenzae meningitis* treated with streptomycin. Three made unconvincing recoveries, but the fourth, after a slow but favourable response became resistant and died in spite of full doses of penicillin and sulphamezathine to which the organism remained fully sensitive throughout.

Dr K. C. Dixon (Cambridge) showed that when the supply of glucose and oxygen was cut off from a cell it used its residual sugar, and when no further energy was available intracellular constituents were liberated into the surrounding tissue. Thus stored red cells liberated their potassium as soon as the available sugar was used up. This potassium being toxic might cause damage to nearby cells early in disease processes. The main effect was produced experimentally by adding 20–30 milliequivalents of potassium. Professor Dorothy Russell (London) thought that if this were true a spherical and perhaps eccentric effect would be seen in the brain when cells were deprived of blood supply whereas in fact a laminar appearance was present parallel to the surface of the brain.

Dr N. H. Martin (London) examined the principles of electrophoresis and demonstrated electrophoretic patterns in normal and abnormal plasma. On physico-chemical data the purified albumin molecule should be the ideal protein for the treatment of shock (unassociated with blood loss) and generalized oedema because of its high solubility, low viscosity, and high osmotic pressure. The globulin fraction when broken down showed a high concentration of antibodies in the  $\gamma$  group, a lipid binding ability in the  $\alpha$  and  $\beta$  globulins, and an iron-binding capacity in a specific member of the  $\beta$ -globulin family.

### SECTION OF PHYSIOLOGY AND BIOCHEMISTRY

Wednesday June 30

#### Recent Work on Proteins

The president of the Section, Professor A. C. Chibnall (Cambridge), opened a discussion on recent work on proteins and its medical applications. At the turn of the century, when the late Sir William Hardy started to develop the colloid chemistry of proteins, only a few workers were interested. In contrast, there were today amino acid analysts, physical chemists, x-ray

crystallographers, and workers in many fields of clinical medicine who were concerned with protein research. Interest was widespread, and the pace of research continued to quicken. Of the many topics which could be discussed that day he mentioned two. Side by side with the work on the differentiation and characterization of the individual proteins of tissues the chemist was gaining some insight into their chemical structure. The overall amino acid composition of many such proteins was now known and efforts were being made to determine the order in which the residues occurred in the peptide chains, the number of such chains in the molecule, and the means whereby the chains were held together. The molecule of insulin, for example, consisted of four chains held together by the S-S linkages of cystine, while the number of chains in the various haemoglobins showed species differences which were paralleled by their immunological specificities. The development of blood transfusion during the war gave a great impetus to work on the plasma proteins, especially in the laboratory of Cohn at Harvard. A new and elaborate scheme of fractionation had made available large amounts of serum albumin in concentrated solution for clinical use. Many fractions representing *inter alia* the blood grouping globulins, complement, gamma-globulins, enzymes, and hormones, were also available in bulk for more extensive study, and certain of these had already been shown to be of clinical value. The present need was for more fundamental research, which would undoubtedly lead to advances in medicine.

Dr J. A. V. Butler said that the great advances in the knowledge of proteins in the last decade were due to improved methods of both isolation and characterization. Now that the conditions of crystallization of proteins were better understood a large number had been obtained in the crystalline state, including enzymes, hormones, serum proteins, toxins, and antitoxins. In order to determine the purity of these products and to investigate their properties powerful physical instruments had been evolved, for example, the ultracentrifuge of Svedberg, the electrophoresis apparatus of Tiselius, and the improved diffusion apparatus of Svensson and Longsworth. These and other methods permitted a fairly full and accurate analysis of the protein constituent of a mixture and enabled the properties of the individual proteins such as molecular weight, size, shape, and charge, to be determined. He gave a brief review of these methods and the results achieved.

#### Plasma and Blood Derivatives in Treatment of Burns

Dr L. Colebrook and Mr P. Dallas Ross presented a paper on the value of serum or plasma transfusions in the treatment of severely burned patients. Dr Colebrook had observed more than 150 cases so treated, many of them children with 10% or more of the body surface burned, the rest adults with 15% or more. In general, the plan adopted had been to forestall haemoconcentration by setting up a drip transfusion as early as possible if the burns were extensive and by keeping it going for twenty to thirty hours. After that time the permeability of the capillaries was getting back to normal, and fluid was being reabsorbed from the tissues. The amount of serum or plasma required for each patient was a matter for careful judgment and constant clinical observation, supplemented by frequent determinations of the degree of haemoconcentration. Transfusion could easily be too timid, on the other hand, it was not difficult, especially with children, to overload the circulation. None of the formulae proposed for regulating the amount necessary should be relied upon. As much as 15 pints had sometimes been required for an adult with extensive burns.

The authors also described experiments bearing upon the value of fibrinogen and thrombin in securing the better adhesion of skin grafts. Grafts of about the size of a sixpence were fixed with dermatome glue on two wooden blocks, and the cut surfaces were then painted with solutions of thrombin and fibrinogen respectively. After opposing these two surfaces, and waiting a few minutes for the clot to join them, the breaking strain was determined with a simple torsion balance. With no glue between the grafts (or a drop of saline) the breaking strength was usually 20 to 30 g, with thrombin and fibrinogen it was usually between 80 and 200 g. One technical point was that a watery solution of thrombin tended to run off the recipient surface before the graft with its fibrinogen could be

placed in position on it. This could be overcome to some extent by using a more viscous solution of thrombin—e.g., in 5% casein. Grafts applied with a glue thus made had taken as well as ordinary grafts. Clinically there appeared to be a definite advantage in the use of a thrombin-fibrinogen glue.

### Protein Hormones

Professor E. C. Dodds gave a brief description of the properties of protein hormones, the first of which to be clearly recognized was insulin. Another important group of protein hormones consisted of those classified under the general term 'gonadotrophins,' obtained either from the pituitary and blood serum or from pregnancy urine. Others less clearly defined chemically were parathormones, the hormones of the parathyroid glands and the other pituitary hormones such as the adrenotropic, pancreatotropic, and so on. An entirely new aspect of biologically active proteins or their derivatives had been opened up by the work of Woolley on streptogenin. Professor Dodds discussed the production of a growth factor for bacteria and animals by the treatment of a protein hormone such as crystalline insulin with proteolytic enzymes.

Professor G. Pickering said it had been known for over a century that there was a close connexion between kidney disease and raised blood pressure. Fifty years ago a protein was discovered in the kidney which on injection into animals raised arterial pressure. This substance, renin, had been shown to be an enzyme (hypertensinogen) which split from a constituent of the plasma globulins a small molecule, hypertensin. Hypertensin was the effective pressor substance. When the renal artery was constricted in animals hypertension resulted, probably from the release of renin into the circulation. The hypothesis that some forms of human hypertension were due to a similar mechanism was attractive, but up to the present unsubstantiated. Renin probably played a part in the regulation of arterial pressure.

The final contribution to this discussion was by Professor N. F. MacLagen, who discussed diagnostic tests based on changes in serum proteins. An important type of change was an increase in gamma-globulin content with or without a fall in albumin. This formed the basis of the flocculation tests, such as the mercuric chloride reaction of Takata and Ara, formol gel, calcium chloride coagulation band (Wetmann), cephalin cholesterol, colloidal gold, thymol turbidity and flocculation, shal-lach red, cadmium sulphate and zinc sulphate turbidity tests. He reviewed the physico-chemical background of these tests. From clinical reports the thymol, gold, and cephalin cholesterol tests appeared to be the best for providing easy and rapid methods of demonstrating the type of change mentioned, which was found principally in diseases of the liver and in certain acute and chronic infections. A desirable combination would be thymol plus one other test. A single accepted test for excess of gamma globulin would be the ideal. This work had many possible applications in protein chemistry and in immunology.

## SECTION OF PREVENTIVE MEDICINE

Wednesday, June 30

### Preventive Medicine under the National Health Service Act

With the president, Dr G. F. Buchan (London), in the chair, a symposium on preventive medicine under the National Health Service Act, 1946, was opened by Dr H. Joules (London), who spoke on the role of the hospital. He said that the district hospital must serve the local community and have the closest contact with local health authority services and with health centres. Preventive medicine was needed in midwifery, gynaecology, ear, nose and throat work, in geriatrics, and in tuberculosis work. There must be close liaison between all the groups working on the problems of child health—with the emphasis on health rather than disease. The present system of notifying diseases should be reviewed and notification should be followed by prompt action. The district hospital should be a common meeting-ground for all health workers in the area, with responsibility for the postgraduate instruction of the practitioners who would ultimately serve in the health centre practices.

Dr W. N. Pickles (Aysgarth) said that the public health service began with the general practitioner. A period in general practice should be recommended for all young doctors, especially those destined for this service. Health centres might help to form a bond between general practitioners and the public health service. Child-welfare centres should be there and in certain instances child-welfare and school children examinations could be conducted by general practitioners, and could also be a part of the training of a paediatrician. Ante-natal examinations, wherever possible, should be undertaken by a practising obstetrician, whether a general practitioner or a trainee specialist. The Act correlated the work of the general practitioner, the health visitor, and the district nurse. Health talks should be given by general practitioners. The link between medical officers of health and general practitioners in epidemiology should be strengthened.

Dr E. D. Irvine (Dewsbury) said that under the Act the medical officer of health was administratively responsible for social medical work, including health education. General practitioners could be helped by health visitors and other social workers. It was important to realize the functions of health visitors such as health education, social amelioration, "intelligence." Information about sickness should be more freely transferable, and its collation in health departments was necessary. Social care and the after-care of sick persons, including the mentally ill, were important new duties for the medical officer. Health education was the key to the prevention of illness, and mass surveys and measures directed to the problems of ageing might be important.

Mr H. J. McCurrah (Hove) suggested that the casualty department of a teaching hospital provided the most important material for the instruction of undergraduates. It was as difficult to be really efficient in general practice as it was in any specialty. Suitable postgraduate courses were essential. The medical officer of health should be head of a special department of preventive medicine within the walls of the hospital, and should leave the sterilizing atmosphere of the town hall for the more stimulating society of his colleagues.

Dr F. Gray (London) said that the real aim of preventive medicine was to keep people well—not to prevent them from contracting one disease while leaving them to acquire another. General practitioners in the future would require a different education and there would have to be closer co-operation between all sections of the profession.

Prof R. H. Parry (Bristol) spoke of the value of the health centre as a common meeting-ground for all sections of the profession, including ancillary workers. Some overlapping of administration under the National Health Service Act was inevitable, and even desirable.

Dr Jean M. Mackintosh (Birmingham) thought the training of the consultant paediatrician in preventive medicine should take place at the same time as he was obtaining his hospital experience. Local authority medical officers should not merely be given the opportunity of attending hospitals, but should be given responsibility for patients.

Dr J. F. Warin (Leeds) referred to "social priority" in hospital admissions, and the importance of leaving final decisions to the medical officer of health, particularly in maternity cases and in cases of chronic illness and infectious disease.

## SECTION OF DERMATOLOGY

Wednesday, June 30

### Occupational Dermatoses

With the president, Dr C. H. Whittle, in the chair, Dr John T. Ingram (Leeds), opening the discussion, emphasized that the occupational dermatoses should be approached along general medical lines and not regarded as something outside the range of ordinary medical practice. The medico-legal complications which beset industrial affairs, the scientific aspect, and the statistical approach seemed to obscure the essentially human character of these diseases. The whole range of health and activities of the patient both in his home and in his leisure hours as well as at work must come under review. Occupational factors concerned the physical and chemical nature of the materials with which the worker came in contact, but regard

must be paid to prophylactic and cleansing procedures, to the atmospheric and other physical characters of the environment in which the man worked, and to the social, psychological, and economic aspects of his position. There were three groups of occupational dermatoses: first, peculiar affections related to particular trades or processes; secondly, traumatic dermatoses produced by gross irritants which would damage the skin of any normal subject exposed to them; a third group was essentially constitutional in character and related to the susceptibilities and fragilities of the individual who might break down under long-continued wear and tear of the skin or who might develop a peculiar personal sensitiveness, with resulting dermatitis. The importance of a patch test in contact dermatitis was stressed and attention drawn to the necessity for treatment of a simple, bland, and protective character. Consideration should always be given to the general health of the patient and to the circumstances relating to his breakdown. It was important that the patient should have the nature of his disease fully explained to him. Charts showing the incidence and age of onset and water colour illustrations of industrial dermatoses were shown.

Dr Sibyl Horner (London) said that she appreciated Dr Ingram's point of view on the essentially human character of the skin infections due to occupation. It was with this aspect in mind that she had concentrated first and foremost on the prevention of industrial dermatitis and, more recently on the reablement of those who were the unfortunate subjects of this condition. Of the broad divisions—selection, protection, inspection, and cleanliness—into which the preventive measures fell, the one most likely to be overlooked was inspection. This was really the key to the success of the other protective measures and made early treatment with all its advantages possible. More use might be made of the principle of minimal contact with skin irritants; this principle, coupled with graded exposure gradually increasing in amount, had also been applied with success in the war to weed out susceptibles on the manufacture and filling of explosives. Reablement of cases of industrial dermatoses was still in its infancy, but it was clear that only by careful attention to this aspect could the present distress and disappointment to the individual and the economic loss to the nation be avoided.

Dr John C. Belisario (Sydney), mentioned a few of the less common conditions encountered in Australia. Solar keratoses and carcinomata were seen particularly in those engaged in outdoor occupations—policemen, seamen, farm workers—and were admitted by insurance companies as industrial hazards. Prophylactic measures related mostly to clothing, but protective agents such as quinine tannate were helpful if used regularly. Dermatitis from mites was seen in those handling figs, dates, cheese, coconuts, and copra. Scrub itch attacked the legs, and mites from grass and soil and from poultry and starlings also gave rise to urticarial rashes. A similar dermatitis from mites might result from the handling of grain, straw, mattresses, and hyacinth bulbs. Dr Belisario also referred to dermatitis from such different types of wool as glass wool, mineral wool, and rock wool.

Dr J. Warnock (Leeds) stressed the importance of friction and mechanical injury in provoking dermatitis. He found that only 10% of claims were in fact serious cases of industrial dermatitis and in only 10% of cases was recurrence common. Many men continued at work, sometimes for years, in spite of the presence of dermatitis. He regarded seborrhoeic dermatitis as industrial if the sites involved were sites of contact and injury. Many cases of pompholyx were industrial in origin. He did not find that those who recovered from dermatitis in one trade relapsed if they went into a different class of work.

Dr Geoffrey A. Hodgson (Cardiff), speaking on adaptation and recovery in occupational dermatitis, said that complete mechanization to eliminate contact and efficient selection to exclude dermatitis-prone persons were utopian ideals. The skin had to be exposed to irritants and to wear and tear. A rough assessment from a series of cases showed that 70% of cases of oil-dermatitis occurred after five years' contact, over 50% of miners' traumatic dermatitis of the legs occurred between 50 and 65 years of age, and housewives' dermatitis from soap and cleansers appeared most often between 41 and 50 years of age. The primary factor of resistance was an intact horny layer. A miner's skin broke down from mechanical injuries, and 15% of

oil-dermatitis cases were preceded by skin injuries. The balance between skin breakdown and epidermal re-formation might be upset by trauma, high concentration of irritants (age in miners) and the menopause (in housewives). There was a natural tendency to re-form the horny layer after dermatitis. In the later stages this was called "hardening," which might occur, according to Schwartz, in spite of men continuing at work. 14% of miners had recovered from previous attacks of dermatitis. After clinical cure, time was needed for full hardening. Bad adaptation and unemployment might cause recurrences from anxiety and habitual scratching, which interfered with the natural tendency to repair. As a corollary of full adaptation suitable work with freedom from unsettling economic hardship was necessary. Chronic incapacity was more likely to be produced by long unemployment than by returning to work too early. Hardening might occur in the face of greater external irritation than was at present thought possible. Medical officers in industry should investigate this point. Patients with dermatitis should be encouraged to return to work at the earliest possible moment to allow convalescence and hardening to occur at work; suitable employment must be provided. First-aid measures for dermatitis and for minor skin disorders should be taught in factories.

Dr W. J. O'Donovan (London) said that he had read the first paper on exogenous dermatitis to be reported in the *British Medical Journal*. He wanted to stress, however, other factors demanding attention, and instanced discharge from the Services on psychiatric grounds and the repetition of fears in the patient's recital.

If a rash came and went while the patient was working, and if parts normally covered were affected, work was not likely to be the cause. Cupidity, revenge, and the desire for retribution might be important. Patients were apt to have fantastic ideas about skin sensitivity. Young girls with a dermatitis which persisted quite often had a pronounced mother fixation. Many an honest diagnosis needed retrospective correction. Factory work was habitually labelled dirty and held responsible for dermatitis in the male. The same conditions gave rise in the female to a skin disease termed eczema—an unjustifiable sex distinction. The "patch-test" was very open to influence by suggestion and he had produced positive reactions with human sweat and normal saline.

Dr A. Thelwall Jones (Widnes) said that occupational dermatitis was the most important occupational disease. The normal routine clinical examination gave no indication of the workers likely to develop some skin disease. He classified cases of industrial dermatitis into two groups: (1) cases of abrupt onset caused by a known irritant; (2) cases of idiopathic character. Prevention was difficult because of lack of knowledge of the disease process. A clean industry and good environmental conditions were desirable. He put in a plea for more hospital beds for these cases to allow of adequate treatment in the early stages.

Dr R. M. B. MacKenna (London) stressed the importance of rehabilitation. There were two classes of case: (1) early cases, which might affect either "green" or "salted" labour and in which it was desirable to keep the patient at work; (2) relapsing cases, in which fears about security played an important part. Where the affection appeared in "green" labour the opportunity of selection arose. In "salted" labour contact should be avoided and not resumed until the skin had hardened again. Desensitization by limited contact might be tried. In relapsing cases all the resources of rehabilitation therapy, physical and psychological, should be employed. Experience of rehabilitation in relation to dermatosis in the Army was encouraging.

Dr Robert Forbes spoke of the importance of respecting the confidential character of the relations between doctor and patient. He discussed the "medical witness of fact" and the expert witness and suggested the desirability of expert witnesses contributing to the solution of these problems by conference rather than in the Courts. Exaggeration and theorizing were to be avoided in giving evidence.

Others who contributed to the discussion were Drs S. W. Fisher (London), F. F. Hellier (Leeds), F. A. E. Silcock (Leicester), J. E. M. Wigley (London), I. M. Scott (London), J. B. L. Tomblinson (Bedford), and E. C. Dawson (Derby). In the afternoon a number of clinical cases were demonstrated and discussed.

## SECTION OF CHILD HEALTH

Thursday, July 1

## Neonatal Mortality and Neonatal Morbidity

The president, Sir Leonard Parsons (Birmingham), began by drawing attention to the new name of the section as reflecting the widening conception of paediatrics. Dr Agnes R. Macgregor (Edinburgh) then opened the discussion on neonatal mortality and morbidity. She said that the basic cause of neonatal death was related to the mother. Paediatric study of the subject was concerned with the effects on the child of maternal conditions and of the hazards of delivery. Reliable post-mortem examinations and close collaboration between pathologist and clinical worker were essential for successful study.

The majority of neonatal deaths fell into one of four categories—developmental defects, asphyxia, intracranial haemorrhage, and infection. More than one of these might occur in association, and it was sometimes difficult to decide the principal cause of death. Prematurity, when of extreme degree, could be the sole cause of death. On the other hand prematurity was overwhelmingly important as a predisposing factor in almost every other condition causing death in the newborn. Atelectasis was almost always due to asphyxia and was rarely itself the cause of death. Death in cases of asphyxia might follow depression of the respiratory centre, or haemorrhage. Inspiration of foreign material was a common contributory cause of asphyxia. The inhalation of vernix was of particular importance in this connexion.

Fatal haemorrhage might take place within the cranium, in the suprarenals in the lungs, or from the surface of the liver. Intracranial haemorrhage occurred in five forms. Direct trauma gave rise to subdural haemorrhage and extradural haemorrhage, which was rare. Intracerebral, subarachnoid, and intraventricular haemorrhage were usually due to asphyxia. Subarachnoid and subdural haemorrhage of moderate extent could be survived. It was difficult to estimate the severity of intracranial haemorrhage which was incompatible with life. Dr. Macgregor emphasized that haemorrhage was not always present when suspected on clinical grounds.

Most neonatal deaths of infants who survived the immediate risks of birth were due to infection. Premature infants predominated among those dying from infection, and of all deaths from infection 90% were accounted for by pneumonia, thrush, and other infections of the alimentary tract. Fundamental research was required to further the prevention of infections which persisted despite precautions.

Professor L. S. Penrose (London) referred to the emphasis given by statistics to hygienic measures as having had the greatest influence on infant mortality. This influence had been less evident in relation to neonatal mortality. Congenital abnormalities contributed considerably to neonatal mortality and were themselves subject to prenatal influences. Separation of these influences according to whether they were hereditary or environmental was difficult to justify. Factors of heredity and environment were not independent. Developmental events should be considered in relation to the time sequence of potential influences. Malformations might have as their source recessive genes of ancient origin, recent 'point' mutations of single genes, chromosomal disruption, adverse intrauterine environmental influences, or a combination of these factors. Usually it was not possible to determine the different causes from human data.

The problem was to foretell the likelihood of a malformed child being followed by children similarly deformed or malformed in some other way. Professor Penrose had found in an investigation into over 100 children born after the first case of malformation in the sibship that 5% had been similarly malformed and that 6-7% had other types of serious malformation. The pedigree only occasionally gave an important clue. A condition transmitted regularly from parent to child suggested a single dominant gene, and was usually slight in character. Rare recessive genes were sometimes detected as a result of parental consanguinity. A negative family history was not proof of the absence of a genetic factor. Foetal infection and antigenetic factors arising from rhesus incompatibility might prove to give rise to congenital malformation. Study of the subject was complicated by the effects of maternal age in relation

to foetal death. Foetal malformations were common at the extremes of maternal ages.

Dr Winifred Young (Epsom) said that the difficulties of the premature infant immediately after birth and the high mortality from asphyxia and cerebral haemorrhage were related to the immature function of the circulatory, respiratory, and nervous systems. The relationship between immature function and mortality from infection was less clear. Lack of immunity, a tendency to under-nutrition, alimentary intolerance, and low renal function were all of significance. The premature infant was able to digest a diet containing her full nutritional requirements. During the first 7-10 days protein intake should be not less than 4.0 grammes and the food should provide not less than 120 calories per day. Where intake was less than that in infants weighing less than 3½ lb, frank signs of under-nutrition might appear and might increase susceptibility to infection.

Professor N. B. Capon (Liverpool) said that physical and "biochemical" trauma might follow the process of delivery. Physical trauma of apparently trivial degree called for accurate diagnosis and treatment. Concussion and compression should be considered where the intracranial contents had been subjected to stress. From the paediatric point of view especial importance attached to the times when the membranes ruptured. Obstetric practice was overcoming the risks associated with breech delivery and anaemia. Professor Capon mentioned placenta praevia and maternal analgesia as causes of biochemical trauma. Avoidance of prolonged labour and readier resort to caesarean section were reducing the paediatric risks attached to placenta praevia. The risks to the child did not justify discouragement of maternal anaesthesia except in special circumstances. The risks were small where care was exercised in the choice and administration of analgesics and anaesthetics.

Dr J. L. Henderson (Edinburgh) described infection as clinically the most important cause of death. Institutional care was associated with special risks. Premature infants were particularly exposed to risk on account of their long stay in hospital. Staphylococcal infection was virtually endemic in many hospitals and might assume a variety of clinical forms. Thrush was met with more commonly in hospital than domiciliary practice and could give rise to oesophagitis and fatal gastritis. The condition of the stools was of little help in the early diagnosis of gastro-enteritis. Listlessness and anorexia were early symptoms. Among urgent needs were improved socio-economic circumstances, extended mothercraft training, improved instruction of students, more prompt reporting of infections by nursery staffs, and the dispersal of mothers and babies in small units. The trend towards increased institutional midwifery was not in the interests of the infant.

Dr W. R. F. Collis (Dublin) agreed with Dr Macgregor on the need for pathological studies. At present our knowledge was ahead of our skill in practical management. Dr Beryl D. Corner (Bristol) said that the risk of intracranial injury in premature infants was lessened when episiotomy was employed at the time of delivery. Rapid aspiration of the mouth and pharynx immediately after delivery was of great importance. The procedure was facilitated by using a laryngoscope for suction under direct vision when the infant was premature. Dr W. N. Leak (Winsford) drew attention to the work of the late Prof. Barcroft. Cardiazol-ephedrine given subcutaneously was of value where neonatal asphyxia was present. In staphylococcal skin infections good results were obtained from a fine suspension of sulphathiazole.

## German Children a Nutritional Study

In the afternoon Dr E. M. Widdowson (Cambridge) and Dr Dean (Cambridge) gave a demonstration of the results of a nutritional study carried out over twelve months on children in a German orphanage. The children concerned had had the bread and cereals of their German rations replaced by bread supplied by the investigators in unlimited amounts and the flour of which had been reinforced with calcium and vitamins. The bread provided 75% of the calories given each child, the remaining 25% being mainly in the form of vegetables. Daily bread consumption by older children was in the neighbourhood of 800 g. The total weekly milk consumption of each child ranged from 250 to 500 ml (about 1/2 to 1 pint). Children included in the examination were subjected to clinical examinations at intervals and to radiological and biochemical

examinations. There was altogether striking improvement in the general physical condition of the children fed on this diet. Height and weight increased coincidentally with great rapidity. Tissue tone, posture, physical activity all showed amazing betterment. There were no digestive upsets and no alterations in bowel habit. Children showing the results of the investigation were demonstrated.

Professor R. A. McCance (Cambridge) said that this study had demonstrated the possibility of securing excellent growth and health on very little milk and little animal protein.

## SECTION OF OCCUPATIONAL HEALTH

Thursday July 1

### Human Relations in Industry

With the president, Dr Donald Stewart (Birmingham), in the chair, Sir George Schuster (Chairman, Panel on Human Factors, Cabinet Committee on Industrial Productivity) said that there were two dangers, that human relations might be treated as a means to an end, and that the subject might be studied in isolation. The ends of industrial activity were to achieve excellence in production, to provide a satisfying activity as the foundation of a good life, and to fit into a satisfying pattern of human society. Good human relations could only be founded on the treatment of each human being as someone of value, whose welfare must be regarded as an end in itself. Workers must be able to find interest, self-satisfaction, and happiness and something more than a way of earning a living in their work, and this was an essential part of the manager's task in human relations. Efficiency in management, both technical and commercial, was an essential condition of good human relations.

The greatest need of modern industrial society was to make industrial employment something which was seen as an essential part of a satisfactory human life; this would not be obtained unless managements were singlehearted in their pursuit of it and efficient at their own production job. Industrial employment must fit in harmoniously with the worker's social state. There was no single solution, and one must beware of cut-and-dried schemes, for the problem needed fresh effort every day. Here there was a great opportunity for a valuable contribution by the works medical officer, whose aim must be the creation of positive health. A full-time medical officer should be employed wherever possible and he should be treated as a member of the management team, taking part in all management discussions, the medical view should be taken on every point in the total plan of plant, premises, and so on. The fact that a medical officer was a specialist should not exclude him from appointment to the highest administrative post if he desired it and had the necessary abilities and qualities, and he must have broad concepts of his own work. Would it be possible to form a group of industrial medical officers with whom his panel or he himself could personally discuss these problems?

### Human Relations and Occupational Health

Dr Elliot Jaques (London) discussed the reasons why preventive measures were not used effectively on the shop floor. Was it because people were irresponsible? Were they innately incapable of taking care of themselves? In the day-to-day practice of the industrial medical officer it often seemed that working people were not concerned about their own health. How could this phenomenon be explained? How could people be expected to behave responsibly? The medical officer was up against the general situation in industry, and had to accept the attitudes in that community. The attitude of the present time based on history and past experience, was suspicion and mistrust. The attitude to new methods for coping with disease would be determined very much by morale inside the works and would be judged by the way in which the medical officer went about introducing these methods. If any scheme was brought down to the shop floor as a *fait accompli* the medical officer was behaving within the accepted pattern of management and it would be resented. He would not be providing opportunity for the workers to participate in handling their own affairs, and certainly the workers' health was their own affair as well as the management's affair. Recent work in the social centres had implications for industrial medical practice

so far as general principles were concerned. Before a group would cope with a difficulty, the group had to feel the difficulty; it was not easy to introduce health measures into a firm unless the workers desired them. All a physician could hope to do was to help people to help themselves, to clarify the problems for them, and help them find therapeutic measures to improve themselves, and until a working group themselves felt a need for coping with its own health problems the medical officer might just have to sit around until the workers came to him for assistance. It was his responsibility to point out the dangers of, for example, lead poisoning and to make himself available to work with the people concerned to develop methods for overcoming these dangers. In other words it was working with people rather than doing things to them or for them which was crucial.

### Education in Human Relations

Dr R. F. Tredgold (Cambridge) said that to see a thing from the point of view of a speaker one depended on logic, to see it from the point of view of the listener one realized that a certain connexion or quality was required to create an emotional reaction in the mind of the listener. It was difficult to bridge that gap and see both aspects at the same time. The fact had to be accepted that logic was not the only factor, sometimes the acceptance of an idea depended much more on the emotional relationship between the speaker and the listener, whether or not the listener always trusted the speaker, and also in the way in which the idea took shape in the listener's mind. It was a question of perspective, one believed much more firmly in an idea and acted upon it if one was under the impression that it was one's own idea. For an idea to be successful the listener must add something to it on his own, and when trying to teach, the whole thing must not be put at once, the listener must arrive at part of the idea himself. Learning occurred as much as a result of the teacher's attitude and behaviour as of his words. The pattern of inter-personal relationships and inter-group relationships was not based on the religious and philosophical views of the past twenty-five centuries, but much more on the historical facts of the one century since the industrial revolution.

Mr Jerome F. Scott (Harvard, U.S.A.) gave details of a course set up at Harvard to study the way of looking at human situations and problems, and the way a leader should think about them. By cold statistical fact it had been proved that the most effective leader was the one who thought of his people as ends in themselves rather than means to his economic ends. This was not so simple as it might seem. There was the illustration of the incentive system working effectively in one firm and not in another. With the introduction of an incentive there was needed a change of a real sort in the human situation. If the working group did not trust their leader it would be ineffective. Individual behaviour sometimes had to be used as clues—a good example of that was absence from work. A worker when questioned would give the reason which he thought would satisfy his questioner. There might be a variety of reasons contributing to his absence. An important factor was how much he wanted to be at work. If there was a group which had more absences than another it could only be explained by looking at the total situation of the group—morale, working conditions, and medical factors. The absences were but an index of the total situation. If a supervisor could avoid emotional upsets on his own part and looked behind unpleasant words and behaviour with an inquiring mind it was much easier to get to the bottom of the situation. If feelings were straightened out facts would take care of themselves.

Dr W. E. Chiesman (London) stressed the necessity of converting the rank and file of the medical profession to interest themselves in the working environment of their patients and their fitness for it and the necessity of the education of youth for industry. Dr Brian Pringle (Dublin) said that with the suggested incorporation of the industrial medical officer into the management team there was a danger that clinical medicine might be neglected and it was essential that the medical officer should carry on a clinical practice in the factory.

Professor Ronald E. Lane said that the industrial medical officer must receive some special training for this work. Sir George Schuster had drawn attention to the large number of small units which would need medical advice if any national industrial medical service was introduced, and this problem would not be solved without the help of the general practitioner who

# VOLPAR

TRADE MARK

## VOLuntary PARENthood

Volpar Gels and Volpar Paste have been prescribed and used on an increasing scale throughout a decade and abundant evidence of their efficacy, acceptability and innocuousness has been produced, confirming the original hopes of its success

Volpar retains its position as the most active spermicide available. It may be prescribed in most cases in which contraception is indicated. Literature will be sent on request.

## 'SULPHAMEZATHINE' ORAL SUSPENSION for CHILDREN

For many bacterial infections in children, 'Sulphamezathine' is the safest and most effective of all the sulpha drugs. It rarely gives rise to unpleasant symptoms, and renal complications are almost unknown. 'Sulphamezathine' Oral Suspension is a palatable orange-flavoured preparation containing 1 gramme of 'Sulphamezathine' per 2 fluid drachms. Children take it readily, and it provides an attractive alternative to 'Sulphamezathine' tablets.

'Sulphamezathine' Oral Suspension is issued in bottles of 100 c.c.

The news that  
DIDN'T get into  
the papers . . .

To the general public, the outstanding topic of 1926 was the General Strike. To the medical profession however, the year was also memorable for another event of far reaching importance.

Until Minot and Murphy discovered the curative value of liver in 1926, little was known regarding the treatment of macrocytic anæmias and prognosis was very grave. Since then the curative effects of liver have been fully proved.

Hepastab Forte is a concentrated extract of liver which has been produced in Boots laboratories after extensive experimental work. Its high purity excludes risk of undesirable reactions following administration and it is painless on injection.

Hepastab Forte is indicated in cases of pernicious anæmia and other megalocytic anæmias. One cubic centimetre is therapeutically equivalent to 4,000 to 5,000 gm. of fresh liver by the mouth.

### unwelcome legacies of summer

Summer-time puts the accent on organized sports and exercise. And the fungi responsible for mycotic skin diseases flourish wherever showers, baths and pools are communally used. To treat the individual case, to halt the spread of infection, or to eliminate the disease from an institution, Mersagel is specific. Mersagel contains the powerful fungicide phenyl mercuric acetate at a concentration of 1/750 in a colourless, water miscible jelly base. It swiftly attacks the responsible fungi and frequently brings rapid regression of symptoms even in previously persistent cases.

## 'GENATOSAN' DERMATOLOGICAL CREAMS

BACTERIOLOGICAL and extensive clinical tests have shown that a wide range of bacteriostatic and fungistatic agents possess enhanced effectiveness in 'Genatosan' water-miscible ointment bases compared with the conventional greasy ointment bases. Advantages of 'Genatosan' Dermatological Creams include the following —

- 1 The medicament rapidly diffuses into the exudate and skin tissues
- 2 Heat radiation from the skin is unimpeded, thus avoiding irritation and discomfort
- 3 The cosmetic texture is not displeasing to the patient due to the vanishing cream base — thus ensuring conscientious use

would need reorientation to be able to do it effectively. It was the duty of the teaching centres to provide this. Mr V. Wilkison (Croydon) suggested that a medical officer could be employed by a group of factories in a similar trade or industry, when he would become conversant with processes, operations, job appraisal, and the fitting of men to the job. Dr J. A. L. Vaughan Jones (Leeds) said that until the management team had the confidence of the worker it would be difficult for the doctor to obtain his true place in industry. The idea of just sitting around was very good once the doctor had the people's confidence, but just sitting around would not gain their confidence.

Sir George Schuster, in reply, said that it was the medical officer's function to give general advice on the way in which industrial processes were carried out taking the medical point of view into account. He should be in close touch with the patients' panel doctor, but unless there was a good industrial atmosphere and complete confidence what he had suggested would break down. He had two major ideas in mind, that industry must be made more industrial-health conscious, and secondly that this industrial society had not evolved a satisfactory pattern of life. This would not come about until industrial leaders had a much greater consciousness of their social responsibilities, and amongst these he put responsibility for the positive health of their employees. The management team should not be regarded as completed unless it included a doctor who really understood the health side. What had been said showed that the conception of the functions of the industrial medical officer required further discussion and clarification. Not nearly enough thought had been given to it, and he hoped it would be possible to carry the discussion further.

## SECTION OF OPHTHALMOLOGY

Thursday July 1

### Ophthalmic Complications in Obstetrics

With the president, Mr O. Gayer Morgan (London), in the chair, Mr F. A. Juler (London) opened a discussion on ophthalmic complications in obstetrics. He reviewed briefly Wernicke's encephalopathy, puerperal septic infections in the mother and orbital haematoma, facial paralysis and damage to the eyeball by instrumental delivery in the baby. He said that in contrast to these rare affections ecchymoses and retinal haemorrhage in the newborn were common. German measles during the early months of pregnancy was now established as a cause of congenital ocular malformation. In his experience retinal arterial obstruction which he thought might possibly be due to spasm occurred occasionally. In cases of hyperemesis gravidarum occurring in the first trimester Wernicke's encephalopathy with retinal haemorrhage might develop. The late toxæmias of pregnancy gave rise to toxæmic retinopathy, the most important ophthalmic complication of pregnancy.

In the classification of Prof. Browne and Miss Dodds there were four groups of toxæmias: (1) pre-eclamptic toxæmia and eclampsia, (2) hypertension in pregnancy, (3) chronic glomerular nephritis in pregnancy (nephritic toxæmia), (4) recurring toxæmia. In group (1) (Miss Dodds) there had been one instance of retinopathy in 46 cases of eclampsia and another single instance in 144 cases of pre-eclamptic toxæmia. In group (2) there had been 10 instances in 65 cases, and in group (3) 2 instances in 17 cases. In 30 cases of retinopathy he had observed personally, most had developed in the last trimester of pregnancy and 2 shortly after labour. Recently A. V. Hallum had claimed that ophthalmoscopically visible arteriolar spasm was present in all cases of pregnancy when the blood pressure had risen above 150/90. In 11 cases of late toxæmia the speaker had followed up after termination of pregnancy; he had found it difficult to detect spasm or to assess irregularities in the vessels. In the puerperium optic atrophy, from loss of blood and septic endophthalmitis were now rare.

In the newborn local penicillin therapy had proved specific for ophthalmia neonatorum. Its value as a prophylactic was less certain. Silver nitrate appeared to be harmless in the concentrations normally used. With adequate antenatal care and no prophylactic drops were needed, in case of doubt silver nitrate should still be used.

Mr Juler was followed by Mr A. B. Nutt (Sheffield). He defined menstrual headache as that type of headache which was usually migrainous in character (i.e., unilateral, preceded by teichopsia), frequently associated with nausea and vomiting and devoid of ocular cause. It often occurred just before the menstrual flow and tended to disappear during pregnancy and at the completion of the menopause. Swelling of the pituitary body had been regarded as the causal factor, but there was also evidence of a disturbance in the anterior-pituitary-ovarian relationship, as shown by disturbances in the gonadotrophin content of the urine before and during an attack. Retention of sodium chloride with consequent oedema of the tissues within the enclosed cranial cavity had been postulated. Recently Zondek and Bromberg had shown that some of these patients were hypersensitive to the steroid hormones. They had obtained good results by specific desensitization.

Extra-genital bleeding ("vicarious menstruation" of the classical writers) was generally met at the beginning or end of the reproductive period, and was more likely to affect women with unstable vascular or nervous systems. The most usual site was the nasal mucosa, but other mucous membranes, including the conjunctiva, might be involved, when "bloody tears" resulted. Oestrogen deficiency and oestrogen excess had both been blamed. Progesterone had been shown experimentally to produce increased permeability of the capillaries in extra-genital tissues, and the skin capillaries tended to become more spastic as menstruation approached, dilating rapidly soon after the onset of the flow. Disturbances in capillary resistance just before or during menstruation had also been observed. A patient with extra-genital bleeding would therefore seem to have vasospasm and increased permeability of the blood vessels.

In the subsequent discussion the significance of German measles as a cause of congenital ocular defects was discussed by Mr P. M. Moffatt (London), Dr G. G. L. Stening, of Melbourne, Mr J. H. Doggart (London), Mr R. F. Lowe (Melbourne), and Mr A. G. Cross (London). Aspects of hypertensive retinopathy in pregnancy were discussed by Dr Jamma V. Dhurandhar (Bombay), Mr A. N. Fergus (Hindhead), Mr J. Berkson (Liverpool), Dr E. G. Recordon (Cambridge), Mr T. Keith Lyle (London) and Mr I. Spiro (London). Dr J. W. E. Cory (Bury St Edmunds) and Mr A. B. Nutt discussed congenital lacrimal obstruction in the newborn.

### Contact Lenses

In the afternoon session with the president in the chair, Mr A. G. Cross (London) read a paper on "The Present-day Position of Contact Lenses". He said that a great advance had been made in 1933 when Josef Dallos published details of a method for taking moulds of the living eye. In spite of subsequent developments it was still impossible to order a contact lens for a patient and to promise that it could be worn with comfort throughout the day. The two causes of inability to wear lenses for long periods were discomfort, which was sometimes the result of a defective fit, and the development of oedema of the corneal epithelium (Sattler's veil). Of 1,850 patients, some of whom had had their contact lenses some years back, about one-third had ceased to wear them. Of those who continued to wear these lenses about 30% were using them for more than eight hours a day and 60% for four hours or more. Nearly 40% of patients with keratoconus and monocular aphakia wore lenses for more than eight hours a day, while only about 25% of myopes did so. Recent developments had aimed at lessening discomfort and eliminating the Sattler veil. It would appear that fitting by stages, introduced by Dallos, would help to overcome some of the difficulties. There was more promise in the elimination of a Sattler veil by using a perforation in the limbal region, as described by Dallos, rather than by changes in the pH concentration of the fluid it produced in the contact lens. A fundamental problem which would have to be solved before contact lenses could be widely used, was to shorten the time needed for fitting. The plastic lenses advocated by Frederick Ridley would seem to enable the lens to be prescribed at one sitting for some 75% of cases. Feinbloom since 1945 had advocated a departure from the "glove fit" to conical fitting, so that the contact lens lay tangential to the sclera at a small area of contact. Prismatic and cylindrical corrections could now be introduced.

This paper was discussed by Dr Jamna V Dhurandhar (Bombay), Dr Margaret Dobson (London) Mr J G D Currie (Cheltenham) Mr Arthur Lister (London), and Mr A B Nutt (Sheffield)

In a paper on 'Optical Aids to the Other Man's Job' Mr J G D Currie (Cheltenham) discussed the optical principles underlying a series of optical appliances

Dr B P H Beattie (Norwich) gave a lucid account of Mendelian principles and their application to ophthalmology. He stressed in particular sex-linked inheritance, distinguishing between recessive sex-linkage dominant sex-linkage and partial sex-linkage. His paper was discussed by the president, Dr Jamna V Dhurandhar (Bombay), Mr Arthur Lister (London), and Dr Margaret Dobson (London)

The concluding paper was by Dr Hugh Ryn (London), who spoke on Nutritional Diseases of the Eye. He drew attention to the high metabolic rate and extensive capillary system of the retina. The suggestion made by Stannus that riboflavin deficiency caused disturbance of the capillary bed would therefore have special significance in relation to the retina. It appeared that some 5% of men in prison camps in the Far East suffered from nutritional eye troubles. The symptoms consisted in blurring of vision difficulty in reading, headache, aching eyes and photophobia. They appeared after 8 to 12 months of defective nutrition. In some patients fleeting scotomata and flickering of vision, or the appearance of haloes around lights and monocular diplopia were observed, they were usually worse in the morning. In some reports oedema of the face had been stressed. Objectively the presence of central or para-central scotomata was a constant feature. Under treatment Harold Ridley had observed the central scotomata breaking up to give para-central remnants, that probably accounted for the difference observed in individual cases. Fundus lesions were usually slight, but multiple haemorrhages and generalized retinal oedema had been recorded.

Thiamine and other preparations containing the vitamin-B complex were considered effective treatment by most observers, but the actual fraction of the vitamin-B complex responsible was not yet known. The results of treatment depended largely upon the stage at which it was instituted. Such little pathological material as was available suggested that the underlying lesion was a primary ganglionic degeneration of the retina with a secondary degeneration of the nerve fibres or alternatively a primary nerve-fibre degeneration with a simultaneous, or secondary degeneration of the ganglion cells. Those findings suggested retrobulbar neuritis, though clinically there were differences in the symptoms of retrobulbar neuritis as compared with the condition seen in camps. On the whole the clinical and pathological evidence would be more consistent with a malnutritional retinopathy than with retrobulbar neuritis. In this connexion the capillary system of the retina and choroid helped to explain the symptoms.

## SECTION OF NEUROLOGY AND PSYCHIATRY

*Friday July 2*

### Epilepsy of Late Onset

With the president Professor E D Adrian, O.M., in the chair Sir Charles Symonds (London) opened a discussion on "The Investigation and Treatment of Epilepsy of late Onset". He said that older writers concluded that in 10% of idiopathic epileptics the onset occurred over the age of 30. Recently the opinion had been expressed that in most cases of epilepsy beginning in adult life the cause was cerebral tumour. Of 400 consecutive cases referred for epilepsy and at that time presenting no clinical signs of a nervous lesion responsible for the fits the age of onset was over 30 in 130. In 74 of those, further investigation or observation provided an explanation: in 21 cases cerebral arteriosclerosis in 13 cases previous migraine, in 11 cases cerebral tumour and in 10 cases a positive family history were discovered. In 56 cases investigations yielded negative results. Of 13 cases with attacks of a focal nature 12 had been traced: 3 had died probably of cerebral tumour and another of unknown causes. Eight were known to be alive and well from two to fifteen years after the first fit, in two cases cerebral thrombophlebitis might have been responsible. Of 43 patients with generalized attacks three had so far proved to

have cerebral tumours. In 28 others no signs of cerebral disease had appeared, and ten years had elapsed since the first attack in 19 of these. In all cases of epilepsy beginning over the age of 30 for which no adequate explanation could be found an air encephalogram and an EEG should be included in the investigations. In patients with focal epilepsy the encephalogram, if negative, should be repeated at intervals if cases of tumour were to be recognized at an early stage.

Dr Denis Williams, considering late epilepsy in the light of knowledge derived from the EEG, traced the changes which occurred after injury to the brain up to the onset of epilepsy. After simple trauma, primary changes, which were confined to the site of the injury, showed immediately in the EEG. They were completely reversible and resolved. At a later date, usually more than two months, secondary changes appeared in the EEG. They sometimes began at the site of the injury; frequently they were bilateral, symmetrical, and perhaps generalized. They were not related to the initial injury in the same way as the primary changes, and in about 50% of cases they were associated with epileptic fits. It was not yet possible to say how many cases in which secondary changes occurred in the EEG later developed epilepsy. Changes of this nature offered some explanation of the failure of surgery to stop epilepsy when the causal lesion had been removed. The EEG also suggested that in some cases the cerebral scar should be extirpated before the secondary EEG changes had developed and the associated fits had begun. A study of those changes would do much to throw light on the processes which occurred in the brain before late epilepsy developed.

Dr D W C Northfield (London) said that, of a series of 139 patients in whom epilepsy developed after the age of 21 years, there were 99 cases of a space occupying lesion (glioma 53, meningioma 17) 21 of other forms of organic disease, and 19 of "idiopathic epilepsy". In the first group fits had occurred in some instances for very many years before other symptoms, while papilloedema was absent in no fewer than 41. A history of progressive deterioration of the various functions of the brain should arouse suspicion of a focal lesion. Where epilepsy was the only disturbance of function ancillary methods of diagnosis in addition to cerebrospinal fluid examination must be employed. Areas of calcification or abnormal vascular markings demonstrated by x-rays not uncommonly indicated the site and nature of a tumour. In the presence of raised intracranial pressure, ventriculography was preferable to encephalography, though the latter might reveal cortical atrophy. Cerebral arteriography was less dangerous than ventriculography and in some cases a local collection of abnormal vessels indicated not only the site but the nature of a tumour. At little risk reliable information could be obtained about innocence or malignancy. When the nature of a space occupying lesion was uncertain and exploratory craniotomy undesirable, aspiration of a small quantity of the tumour through a hollow needle introduced through a suitably placed burr hole yielded material for histological examination which might suggest appropriate treatment. Of 17 patients with meningioma, epilepsy had ceased entirely in 7, while in 53 patients with glioma it had been abolished in only 3.

With regard to radiological examination, Dr James Bull (London) said that in the majority of cases straight x-ray examination was of little value. Calcification of the pineal gland occurred in 50% of persons over 25, and displacement, if present, was of diagnostic value. The size, shape, and character of pathological intracranial calcification, when seen, would give a clue to the nature of the lesion. The bones of the vault should be studied for signs of meningioma or metastases, and, if no information was obtained from such an examination encephalography or angiography must be undertaken. Particular care must be taken to fill the temporal horns at encephalography; otherwise a tumour might be missed. By the percutaneous method angiography was a simple and reliable procedure. Even if all radiological examination were negative repetition might be desirable later. Dr Macdonald Critchley (London) drew attention to various clinical points in distinguishing idiopathic and symptomatic epilepsy. In the former, petit mal frequently alternated with grand mal and the epileptic personality was usually present. Symptomatic fits often resisted average doses of sedatives. The value of the water-pituitary test should not be forgotten. A personal history of migraine was not a

satisfactory explanation of epilepsy developing in later life. Epilepsy did not occur in healthy old age. Senile fits either had an arteriosclerotic basis or indicated senile dementia. Among symptomatic causes old infantile hemiplegia and the withdrawal of sedatives after prolonged sedation should not be forgotten.

Dr Ronald Jones (Ipswich) drew attention to epilepsy complicating cardiac disorders and mentioned two cases in which fits had followed coronary thrombosis. Dr S. Silverman (Birmingham) said that in a series of 26 cases of epilepsy beginning in the late twenties and onwards, 10 were associated with pregnancy and uterine disorders. Dr J. D. Spillane (Cardiff) stated that idiopathic epilepsy appearing for the first time in a person over the age of 40 was not very uncommon. The attack was frequently of an unusual type without convulsion.

#### Senile Deterioration

In the afternoon Dr J. H. Sheldon (Wolverhampton) opened a discussion on 'The Early Recognition and Management of Senile Deterioration'. He surveyed the symptoms as distinct from signs and pathological changes preventing 477 elderly people in a Midland industrial town from living full lives. Prominent among these was limited power of locomotion with a maximum radius of half a mile. Such limitation might be occasioned by arthritis, pain in the feet or dyspnoea, and the incidence of these was constant for each age group over 65, or by vertigo, fear of traffic, lack of desire and general weakness, the incidence of which increased with advancing years. General weakness was the commonest single factor. It was usually first noted around the age of 70 and affected women more than men. Its aetiology was varied, but cardiac weakness played a large part in its production. Difficulty in locomotion in the dark, unexplained liability to falls, vertigo, and increasing deafness were symptoms frequently encountered over the age of 65.

Lack of interest, rambling speech, and suspicion were early signs of senescence, and their percentage incidence increased with age. The frequency of fear, depression and loneliness was constant in each age group. So far as treatment was concerned it was important to retain the old person's interest in life and to maintain as great activity as possible. Old people should be permitted to wear out and not rust out.

Dr Macdonald Critchley (London) said that gerontology was neglected in this country until a decade ago. Recent interest in the subject was due to appreciation of several facts. The percentage of elderly people in the population was increasing. The facilities for the care of the aged were appalling. Compulsory retirement at 65 was depriving the community of a national asset. Research might shed light upon the essential nature of ageing and so conceivably lead to extension of the span of healthy life. Moderate living diminished this risk of early ageing, but abuse of alcohol and tobacco and sustained heavy work after 45 decreased the expectation of life. Indeed the length of life was inversely proportional to the rate of living. Wisdom offset decreased agility, and the elderly should continue in employment for as long as possible.

Mrs A. V. Hill regarded senility as a very loose term embracing (1) Senile dementia. These patients could only be dealt with in a manner suitable to younger insane people. (2) The natural ageing of people of weak intellect. Such patients were usually quiet and inoffensive. (3) The ageing of those often gifted but somewhat unbalanced in their tempers who showed less tolerance and poise in old age. These were the cranks and they found community life difficult. (4) The simple senility of old age. These were ordinary people whose minds and bodies were wearing out unaccompanied by any specific disease. The early signs included forgetfulness, silence, repetition, irritability, and lack of control of bodily functions. Bowel consciousness was a common and unexplained characteristic. Living permanently in bed surrounded by people of similar mentality was always undesirable and in treatment the aim should be the maximum of freedom. The old person should do as much as possible for himself and he should take risks even to the extent of losing his wits.

Dr Trevor H. Howell (Purley) reviewed his findings in a series of healthy Chelsea Pensioners. The range of temperature was wider than in early life, ranging only 96° or 97° F. The pulse rate was variable, ranging between 50 and 100 per minute. Contraction of the pupils to light was present in 64%, and to

accommodation in 44%. Tendon reflexes became increasingly difficult to obtain with age and the ankle jerks were only elicited in 30%. Plantar responses were normal in 95%. Joint position sense was usually normal, but vibration sense showed several variations. Many, though they could behave rationally, had dulled perceptions and slow mental processes. Physical treatment of disabilities should precede other forms of therapy, and general rehabilitation should include remedial exercises, simple games and occupational therapy. Once an old person's self-respect had been restored much had been done to retard the process of mental and physical dissolution. Dr Felix Post (Edinburgh) thought that the early emotional reactions of aged people should be looked for and treated. It was desirable that senescence should be detected before the advent of definite changes and it was feasible to apply ordinary psychological tests even to patients with senile dementia. By placing the patient in a better position emotionally, senile deterioration could be delayed in its onset and mitigated in its manifestations. The aged should be encouraged to take an active part in national life.

Dr H. F. Maudsley (Melbourne, Australia) said that early diagnosis and treatment were rendered difficult by the inability of relatives to recognize early symptoms. Advice was only sought when the patient became difficult to manage at home. Mild injury commonly provoked senile changes, and injury into past history would frequently reveal some prior emotional or personality change. Dr A. Harris (London) stressed the desirability of providing a suitable environment for the elderly.

## SECTION OF NUTRITION

Friday, July 2

### Importance of Proteins in Nutrition

With the president Professor R. A. McCance, F.R.S. (Cambridge), in the chair, Dr D. P. Cuthbertson opened the discussion with a paper which included a review of the nutritional value of proteins, followed by an account of their special significance in convalescence. At present protein usually formed 11-12% of the diet for adults and 13-14% of that for children. American troops included these proportions in their diets when allowed free choice of food in widely different parts of the world. The old dictum still held "If you take care of the calories the protein will take care of itself." Antibody properties were concerned with specific modifications of the globulin molecule, although there was no clear connexion yet between the plane of nutrition and the antibody response. Protein loss occurred in most illnesses and resulted also from trauma and misuse. Adequate dietary protein was therefore most important during convalescence, while debilitated patients who were to undergo operation benefited by a preparatory period on a diet rich in protein.

Dr Harnette Chick (Cambridge) spoke on the supplementary actions between different proteins. In the past individual proteins had been assigned 'biological values' according to their ability to support growth or promote a positive nitrogen balance when given singly in experimental diets. In another system 'chemical scores' had been awarded, in relation to egg protein with a maximum score of 100, by deducting points according to the degree of deficiency of the particular amino-acid most lacking. Recent experience, however, had shown that when two or more proteins were consumed simultaneously the weaknesses of one might be made good by the others. The biological value of a mixture of proteins therefore might greatly exceed the values of any of the components. The time-honoured combination of beef-tea and white bread was found in experiments with rats to provide a good illustration of this phenomenon. Beef extract, although a good source of the amino-acid lysine, was deficient in tryptophane and tyrosine, and could not by itself support growth. Bread being deficient in lysine supported only slow growth. On a combination of bread with beef extract or an equivalent amount of lysine in the form of gelatin, rapid growth was secured. Other examples of supplementary action were found between the proteins of the juice and the solid fraction of potatoes, and between those of cereals and soya-bean meal.

Dr T. Gillman (South Africa) commented that the two preceding communications had emphasized how difficult it was to

predict the effect of various possible supplements intended to improve the nutrition of malnourished native populations. He considered that nutritional diseases might be due largely to peculiarities in metabolism imposed upon the organism by the content of the diet rather than to simple deficiencies. The fact that diseases might be cured by some nutrient could not be taken as proof, therefore, that the disease was originally caused by deficiency of that nutrient. Good growth, moreover, could not always be accepted as an index of good nutrition, since adequate growth seemed to be a prerequisite for the manifestation of many deficiency diseases.

Miss E. M. Widdowson (Cambridge) described investigations on wheat flour of various extractions as a source of protein for growing children. In a German orphanage 150 children aged 5 to 14 years who were much below average weight on account of undernutrition, were kept for a year on diets in which 75% of the calories were supplied as bread. Some children received bread made from whole-wheat flour, for others flour of 85% or 70% extraction was used, while other groups were given bread made from the white 70% flour reinforced with B vitamins to represent 85% or 100% flour. In all groups adequate amounts of calcium and of vitamins A, D, and C were given. The remainder of the diet consisted mainly of vegetables and some jam, but small allowances of milk, meat, fish, and cheese provided a total intake of animal protein of not more than 7-8 g daily. All the children grew rapidly and improved greatly in their general health. Miss Widdowson supported her statements by exhibiting five girls of different ages who had been subsisting on different diets. Although under the particular conditions of this experiment the degree of extraction or reinforcement of the flour had no effect on growth or health it was emphasized that this finding might not necessarily apply under other circumstances. Since the children received only small amounts of sugar and hardly any fat they were able to eat very large amounts of bread, averaging 800 g daily, which corresponded to 65 g of protein.

#### Protein Deficiency and Liver Disease

Dr L. E. Glynn (Taplow) discussed the influence of protein deficiency on liver disease. In experimental animals deficiency of protein had been found to increase the susceptibility to many poisons, including arsenic and carbon tetrachloride. Conversely, resistance to poisoning was increased by raising the protein allowance. The protection afforded by protein supplements appeared to be due to the cystine and methionine which they contained. The fatty infiltration and massive hepatic necrosis that might occur as a result of dietary protein deficiency, even in the absence of exogenous toxins, were also attributable largely to deficiency of the same two amino acids, which were both valuable as sources of labile methyl groups.

#### Agenized Flour

Sir Edward Mellanby, F.R.S., showed his interesting film on canine hysteria produced by flour treated with nitrogen trichloride. He explained that the disease was developed as an unwanted complication in his experimental dogs. Early symptoms were nervousness and difficulty in co-ordination. Later, in typical attacks, the animals rushed round with constant barking, and afterwards developed epileptiform fits and exhaustion. He had traced the cause of the disease to the inclusion in the diet of flour which had been improved by the "agen" process. When the flour was "agenized" to the extent customary in milling flour for human consumption in this country or in the U.S.A. the dogs had hysteria within a few weeks but with very heavily agenized flour the symptoms could be made to appear after only four hours. The toxic agent had been shown to be a component of the protein fraction. No structural abnormalities had been detected in the central nervous systems of the dogs but lesions were commonly present in the intestinal tract.

Dr T. Moran (London) pointed out that in Mellanby's experiments the flour had contributed some 80% of the total calories in the diet. Experiments in America, however, had shown that when dogs were given agenized flour as 30% of their calories, which was about the level of intake in human dietaries, no abnormal symptoms were observed even after six to seven months.

#### Afternoon Programme

During the afternoon the chair was taken by Dr F. Prescott (London). A film on lambing in relation to the feeding of the pregnant ewe was shown by the staff of the Rowett Institute (Aberdeen). Dr Amaro Barreiros E. Santos (Portugal) followed with an occasional paper on "Neuro-endocrine Disturbances and Disorders of Metabolic Balance after Psychic Trauma in the War".

The following demonstrations were given: R. A. McCance and E. M. Widdowson, exhibition of German children; S. R. Sengupta (Aberdeen), resistance of mice on different diets to tuberculosis; E. Lester Smith, K. H. Fantes and L. F. J. Parker, purification of anti-pernicious anaemia factor; C. C. Ungly (Newcastle upon Tyne), clinical trials with anti-pernicious anaemia factor; F. Blakemore and T. Moore (Cambridge), blindness in cattle resulting from vitamin A deficiency; T. Moore, combined deficiency of vitamin E and protein in rats; E. Kodicek (Cambridge) and P. D. F. Murray, the effect of partial vitamin C deficiency on muscles and joints in guinea pigs; K. M. Henry, S. K. Kon (Reading), C. H. Lea (Cambridge) and J. C. D. White (Ayr), lysine in the deterioration of the proteins of dried skim milk on storage; K. M. Henry and S. K. Kon, cystine and methionine as limiting amino acids in milk; K. M. Henry and S. K. Kon, supplementary relationships between dairy products and other foodstuffs.

The proceedings were concluded by a visit to the Dunn Nutritional Laboratory (Director, Dr L. J. Harris) where methods for the estimation of vitamins were demonstrated.

### MEDICAL PRACTICES COMMITTEE

#### England and Wales

The Minister of Health has appointed the following to be members of the Medical Practices Committee for England and Wales. Their offices will be at Devonshire House, Mayfair Place, Piccadilly, London, W1. The seven medical men are all general practitioners.

Chairman: Dr W. E. Dornan (Sheffield). Members: Dr J. A. Pridham (Weymouth), Dr Annis C. Gillie (London), Dr J. F. Murphy (London), Dr D. T. MacDonald (Belford, Northumberland), Dr D. B. Evans (Wrexham), Dr P. V. Anderson (Shildon, Co. Durham), Mr H. Lesser (Chairman of London Executive Council), Mr R. Wilberforce (Barrister-at-Law, London).

#### Scotland

The Secretary of State for Scotland has appointed the Scottish Medical Practices Committee under the National Health Service (Scotland) Act, 1947. The Committee's offices are at 12 Carlton Terrace, Edinburgh 7.

The Chairman of the Committee is Dr A. F. Wilkie Millar, of Edinburgh, who is a former chairman of the Scottish Committee of the B.M.A. The members are: Dr I. D. Grant (Glasgow), Dr W. Jope (High Blantyre, Lanarkshire), Dr J. R. Anderson (Fortrose), Sir William Marshall (Chairman, Lanarkshire Executive Council), Mr H. A. Shewan (Advocate, Edinburgh).

Each Medical Practices Committee will consider applications by doctors to undertake general practice under the National Health Service in an Executive Council area. It will also, on request by a medical practitioner, advise whether a proposed transaction concerning a medical practice involves consideration for goodwill.

Problems of the war-handicapped child will be studied by educators and psychologists from nine countries at a conference sponsored by Unesco to be held at Trogen, Switzerland, on July 5-11. Some 24 delegates, including directors of children's villages, will attend the meetings and will exchange views and experiences on the best methods of fitting war-handicapped children for normal life. Each delegate will present a report of his experiences and the combined reports will form the basis of a study of war-handicapped children to be prepared by Unesco. Representative will be present from Belgium, Denmark, France, Greece, Hungary, Italy, the Netherlands, Poland, and the United Kingdom. This will be the first Unesco sponsored conference to which a German expert observer is invited.

## Correspondence

### Cervical Sympathetic Paralysis

SIR—In their interesting historical account of cervical sympathetic paralysis Dr J Donaldson Craig and Mr R C Fuller do not refer to the observations of Jonathan Hutchinson, who in 1875 (*Illustrations of Clinical Surgery* Plate XXXIV p 203, London) noted that the small pupil associated with what was then called vasomotor paralysis was not in a state of spasmodic contraction but unable to dilate when shaded. The upper figure of the plate shows the eyes in full light, the lower one when as much shaded as possible consistently with the artist's convenience. In the former the two pupils are of equal size, in the latter the right pupil is twice the size of the other. The patient had a left cervical sympathetic paralysis together with a flaccid paralysis of the whole upper limb on that side, following a fall on head and shoulder—evidence, as Hutchinson remarks, that in these cases "the nerves give way at their roots and not in any part of their trunks." This paper which contains many interesting observations, deserves mention in any account of the subject—I am, etc

London W 1

C P SYMONDS

SIR—In their article on this subject (June 19, p 1182), Dr J D Craig and Mr R C Fuller describe the details of Horner's syndrome with meticulous care. On two minor points I should like to join issue with them. They state that what might be described as the reverse of a Horner's syndrome—viz, the stage of stimulation of one side of the cervical sympathetic system as described by Nicati—is "rarely," if ever, seen in present clinical practice, but should be borne in mind as a possible source of confusion in diagnosis. In an investigation which I reported in *Brain* (1945, 68 98), I did not find that this condition was the rarity they claim. Indeed I could not collect 50 normal controls to compare with a series of pupillary inequalities investigated without discovering three who had on close inspection slight inequality of the pupils. Some of these inequalities were due to transient causes, and it was impossible to say with confidence that they were not from stimulation of one side of the sympathetic system rather than transient block of the other side. They were not due to any abnormality of the parasympathetic system nor to permanent sympathetic paralysis for the pupils dilated equally well with cocaine and adrenaline drops. At least one case was demonstrably due to sympathetic stimulation, as the side which was affected was known.

Secondly although the authors describe the vascular changes in Horner's syndrome as variable, because "with the passage of time compensatory mechanisms are brought into play," they describe the pupillary changes as constant. This is not the case, unless the term "constant" is taken in a comparative sense. In one of the cases illustrated by photographs in the same paper in *Brain* it is shown that in the pupils too, compensatory mechanisms may develop. This has been recognized before and has been attributed by Magitot and others to an increased sensitivity of the pupil to circulating adrenaline. The affected pupil, however does not enlarge when cocaine and adrenaline drops are applied, and it seems more likely that the mechanism is one of central inhibition of the parasympathetic centre. The true nature of the condition is then shown only by testing with eye drops.

These small points, like the details in the authors' article, are of importance only in so far as they reflect our understanding of the mechanisms involved in pupillary inequality. With the increasing interest in surgery of the sympathetic system and in particular in the phenomenon of recurrence of Raynaud's disease after sympathectomy, it may be that such details are of more than academic importance.

In few sites can the balance of the two opposing forces of the autonomic nervous system be as clearly observed as in the pupils and nature has for good measure, thrown open the curtain of the iris to the winds of man made folly. Sympathectomists might well turn to the pupil to see demonstrated in two dimensions the problems they are trying to solve—I am, etc

ROBERT L. LARK

ERIC A. TURNER.

### Lower-segment Caesarean Section

SIR—I agree with Mr Bryan C Murless (June 26, p 1234) in his condemnation of Willett's forceps for extracting the foetal head in lower-segment caesarean section. I have known a nasty scalp wound to be caused by this barbarous instrument which subsequently became septic and seriously endangered the infant's life, though thanks to penicillin it recovered. Neither is extraction by the operator's hand or by the single forceps blade satisfactory, especially if the head is deep in the pelvis. Wrigley's forceps are too short and have in my opinion the great disadvantage that they have no screw which can be tightened to keep the blade applied to the head, so that it is liable to slip when traction is made.

Since first performing this operation in 1929 I have used the same method of extraction and found it invariably satisfactory. I use a Haig Ferguson forceps (though I doubt not any other forceps possessing a screw would do equally well). The right blade is applied first on the left side of the mother's pelvis, and with the concavity downwards. The left one is then applied on the other side, the blade locked and the screw adjusted and tightened. All this is done without any hurry, and the head is slowly delivered. Of course, if the head is in the transverse diameter of the pelvis it should be rotated so that it lies antero-posteriorly with either occiput or face presenting in the wound. The blades are then applied, as they always should be, over the ears. The essential point in this procedure is the tightening of the screw before attempting traction. The head is always easily extracted even though it lies deep in the pelvis—I am, etc,

### Prevention of Tuberculosis

SIR—In the leading article (June 19, p 1189) on the Prophit Survey carried out by the Royal College of Physicians you underline a plea made by the President that further efforts should be made to prevent those suffering from pulmonary tuberculosis from transferring their bacilli to other members of the community. According to your leader writer this problem is an epidemiological and social one and might well form the main future task of medical officers of health who should concentrate their attention on the prevention of this disease. Surely this advice is misdirected and misleading. Medical officers of health have for long been fully aware of this problem and have made continuous efforts to cope with it. Many medical officers of health charged in 1930 with the provision of residential treatment also, were increasing their knowledge of the whole problem in an integrated fashion. Now there is a splitting of responsibility again and it becomes the duty of Regional Hospital Boards to make arrangements for the necessary institutional treatment of tuberculosis.

Before the 1939 war London had approximately four beds for every three deaths annually from tuberculosis (about 4 000 staffed beds in sanatoria and hospitals throughout the country for approximately 3,000 deaths). During the war the available beds declined because of bombing and shortage of staff. Pre-war the accommodation was barely sufficient, but it did enable that bugbear of tuberculosis schemes—the waiting-list—to be virtually abolished. Now the waiting-list is much swollen, and with the probable further loss of beds through those beyond the Home Counties being taken into use locally, and with the merging of the always worse waiting-lists of the counties adjacent to the capital with the London list, the control of tuberculosis in the Metropolis may become more difficult than ever. In these circumstances it seems useless to urge the medical officer of health to do more to prevent the spread of the disease. How is he to proceed in the crowded home when a positive-sputum member of the household waits for months for a vacancy in a sanatorium, and when in another family, or even in the same sufferer with advanced disease cannot be offered segregation in hospital? Surely the main burden of preventing the spread of infection resides primarily with the hospital authority whose duty it is to provide sufficient institutional accommodation.

Regional Hospital Boards are facing one of their gravest problems here, particularly in view of the special difficulties of staffing tuberculosis sanatoria. It is not easy to see where

additional nursing staff is coming from. The best use must be made of our limited resources. Much can be achieved by the efficient organization of tuberculosis arrangements at both regional and hospital level. And it would help immediately and enormously if every large general hospital, both teaching and non-teaching could be induced to open a male and a female tuberculosis ward. No big hospital can avoid having odd cases of phthisis passing through its wards. Better by far to nurse these in wards properly organized for the purpose and thus reduce the chances of infection of staff and possibly other patients. The training of nurses and of medical students would benefit and the great increase in the total number of beds available for the disease would go far towards solving this grave problem—I am, etc.,

London N.W. 11

F J BENTLEY

### B C G Vaccination

SIR—In their communications (June 12 pp 1126 and 1129) in support of B C G vaccination both Prof Arvid Wallgren and Dr H Malmros quote the investigation by Hyge of an outbreak of tuberculosis in a girls' school, the former citing it as the investigation which perhaps best corresponds to an animal experiment and the latter claiming it as that which would seem to furnish the best evidence hitherto advanced for the efficacy of B C G vaccination.

In 1942, within a month or two of the time that Hyge was vaccinating his school children with B C G, my colleague, Dr J S Paterson, and myself were vaccinating a number of heifers with the vole bacillus and placing them together with unvaccinated controls in a dairy herd which had a bad record under the Tuberculosis Order. From time to time animals were returned to the laboratory in pairs including one from each category, and the last four animals were not slaughtered for examination until the end of 1947 by which time Hyge had concluded and published his observations. For the first two or three years the advantage lay very markedly with the vaccinated animals. No control was free from infection after eighteen months while two of the vaccinated animals were still completely resistant after three and a quarter and three and a half years in the herd. Over the series only 5 out of 11 vaccinated animals were infected, as contrasted with 10 out of 12 controls, but of the 5 infected vaccinated animals 4 were severely affected and in 2 of these the lesions were even more severe than the lesions found in any of the controls.

Our results bore some resemblance to those which Watson reported to the Twelfth International Veterinary Congress in 1934. Vaccinating calves with B C G against the risk of natural infection, he found that when his animals reached maturity the lesions in infected animals were even more severe than in the vaccinated animals than in the unvaccinated animals.

The end results of vaccination are still far from being established. The mortality rate might be reduced in one age group only to be raised again later in life, possibly after an interval of many years. In the meanwhile the morbidity rate based on clinical observations might be deceptive for the fully virulent tubercle bacillus might have gained access to the tissues and be lying in a state of latency. This possibility is no flight of fancy for I have recovered the bovine bacillus from a vaccinated animal in which there was no trace of any visible lesion two years after it had been infected with a massive test dose of bovine bacilli administered by mouth. Perhaps Hyge has arranged to follow the after-history of all his school-children for the next twenty years. If he has not I feel that he should try to do so for the final observations in such an investigation would carry weight—I am, etc.,

Cambridge

JAMES A YOUNG

SIR—B C G vaccination by Wallgren's intracutaneous method, especially when left to nurses produces local results which are quite strong deterrents when observed by a community still not fully converted to the advantages of the vaccination. The ulceration or "pock," although in cases I have observed not larger than those to be met with in calf-lymph vaccination remains open much longer. The average period for the "pock" to remain moist is 6-8 weeks, with some, not secondarily infected, going on as far as 4 or 5 months. Where a pock was open for less than 3 weeks the vaccination was

likely to prove unsuccessful. (These figures are derived from about 2,000 vaccinations carried out by the Danish Red Cross on D P's in Schleswig Holstein in 1947.) Further, there are 4 cases out of the 2,000 where subcutaneous inoculation has resulted in a sinus persistent after 11 months.

Under these circumstances I would like to ask whether Parish's multiple pressure<sup>1</sup> method of vaccination has been tried with B C G. It avoids the objection to Birkaug's apparatus in that sterilization is very simple—it is very much safer in the hands of nurses, and I think it likely that the public resistance to it would be much less than to the intracutaneous method—I am, etc.,

<sup>2</sup> Mole R H *Lancet* 1947 1 597

SIR—The articles on B C G vaccination (June 12, pp 1126 and 1129) by Prof Arvid Wallgren and Dr H Malmros were most stimulating and encouraging. It seems to be conclusively proved that B C G vaccination is not harmful and that it may be of great benefit in anti tuberculosis work. There are many ways in which it could be used in this country, and one of the most obvious is that of protecting contacts in those homes where, because of shortage of beds, sputum-positive cases have to be nursed for long periods. B C G vaccine should now be available for use in this country—I am, etc.,

Stanstead Abbots Herts

B COUITS

SIR—I congratulate you on continuing to publish articles on the use of B C G vaccine. I think we all agree that it has now been thoroughly tried out in the Scandinavian countries, that it is harmless if used correctly, probably cuts down the incidence of pulmonary tuberculosis, and is especially useful for contacts and young nurses.

In view of the shortage of sanatoria staff and lack of facilities to take infectious cases of pulmonary tuberculosis away from uninfected contacts it is doubly important to use this method in England if there is the slightest hope that good may be done. Our tuberculosis officers in Bedfordshire, who are keen and competent young men, are anxious and willing to use the vaccine in the county. The only stumbling block is the Ministry of Health, who presumably acting on Prof Wilson's advice, will not supply the material and it cannot be obtained through our commercial houses—I am, etc.

### Chances of Survival in Pulmonary Tuberculosis

SIR—In your annotation on the above subject (June 12, p 1143) you finish by stating that the figures for Aberdeen would have been of more value if the number of persons who were lost sight of during the period of observation had been stated. You may therefore be interested to learn that of the 1257 patients, 26, or 2.1% of the total, were lost sight of. Details are shown in the table below.

12 were lost sight of during the 1st year of observation				
5	"	"	2nd "	"
2	"	"	3rd "	"
1 was	"	"	4th "	"
4 were	"	"	5th "	"
1 was	"	"	6th "	"
1	"	"	7th "	"

One of those in the fourth year died of bowel obstruction unassociated with his tuberculosis, and the one in the sixth year was killed by enemy action. Of the 26 cases, 16 had been classified as Stages 1 and 2 and of these 9 were lost sight of during the first year.

The article from which the figures were taken was, of course, a report on a paper delivered to the Tuberculosis Society of Scotland, and the number of patients lost sight of was regarded as being so small as not materially influencing the figures—I am, etc.,

Aberdeen

ROBERT FRASER

### General Use of Tuberculin Test

SIR,—We are all in debt to the organizers and to the Prophit scholars for their skilled attack from an epidemiological angle on the disease which alone causes approximately 40% of deaths occurring in the age group 15-24. It is however, in reference to the policy suggested in your leading article (June 19, p 1189) a policy which might be adopted by those responsible for health supervision in young adults that I should like to discuss certain points. How far is it practical even with an aim so important as the early diagnosis of tuberculosis to keep all young adults under general medical surveillance, to carry out graded tuberculin testing, and when necessary x-ray them? Among contacts, medical students, or nurses, where a special risk of exposure is recognized it may be reasonable and is in any case likely to be demanded because of their special knowledge of such matters. Among healthy young adults, whether in industry, the armed Forces, at the university, or elsewhere, the problem is different. In proportion to their intelligence they require an explanation of the reasons for carrying out the Mantoux test, and this entails giving information from which the seeds of anxiety might grow.

If 60-85% of these young adults are Mantoux positive there are few health services equipped to carry out full-size chest x-ray examinations on so large a proportion. If the proportion of Mantoux negatives were more than a small one, follow-up testing of Mantoux negatives at four-monthly intervals would not be feasible with present facilities and if the interval is longer the procedure loses value. Before advising the general introduction of Mantoux testing for all young adults, would it not be wiser to restrict its use to annual surveys until such time as the position in this country approaches if it ever does the present situation among university students in the USA where at some universities only 10-15% are positive reactors? Because this proportion is manageable, the general policy in the USA is to prefer the Mantoux test to x-ray examination as the routine, but these circumstances do not apply in this country. Here it would as yet be premature in my opinion to attempt to apply the Mantoux test to the general population for the purpose of controlling tuberculosis as opposed to that of carrying out a survey. There is an additional advantage in waiting. More information may become available concerning the value of the test when high dilutions are used. If the proportion of positives should remain high in this country the best use of the test might well be as a test of sensitivity in contrast to its current use to determine the presence or absence of living tubercle bacilli in the body.

At the present time we stand in particular need of published information concerning the proportion of Mantoux-positive young adults among groups of the population who are not exposed to special risk of infection. During a recent pilot investigation here on 41 undergraduates of average age 22.5 years 35 showed a positive reaction (consisting of oedema up to 5 mm diameter with surrounding erythema) to 0.1 ml of 1:10,000 dilution of old tuberculin—I am, etc

Oxford

R. W. PARNELL

### Xanthelasma Palpebrarum, Gallstones, and Atheroma

SIR—Xanthelasma palpebrarum probably a manifestation of a regional disorder of cellular lipid (cholesterol) metabolism, is I think the commonest external cholesterol lesion met with and is on the whole more frequent in females and in certain families, less frequent in those of purely British ancestry than in those of foreign or partly foreign ancestry. Its connexion with other types of xanthomatosis is of course well known, and I think that there is often noteworthy frequency of arterial atheroma and gallstones in the same families—probably indicating the presence of other associated (local and systemic) errors of cholesterol metabolism.

I knew three brothers big men fond of open-air exercise especially shooting. The eldest of the three, a merchant, lived in a healthful way largely in the country and died at 72. Towards the end of his life there were aortic and mitral murmurs probably atheromatous and then suddenly he developed enormous cardiac dilatation. His younger brother in early middle age had a severe cardiac attack when playing

cricket and then was found to have aortic regurgitation possibly due to rupture of an atheromatous valve. He died relatively early. The youngest of the three brothers, an architect, died at 70 or 71, apparently of coronary thrombosis. He had rather striking xanthelasma palpebrarum and one of his daughters was operated for gallstone. A niece (sister's daughter) of these three brothers had slight xanthelasma palpebrarum at about the age of 20 but it had disappeared by 55 and she is now in excellent health at 79. The father of the three brothers died (pneumonia) at 78, and the mother lived to 94. Incidentally this history shows that a family tendency to xanthoma and atheroma does not necessitate early death. It illustrates points to which I wish to draw attention but is by no means an extreme example. There must be hundreds quite as striking or more so—I am etc

### Golden Jubilee of the R.A.M.C.

SIR—I have just read your leading article in the *B.M.J.* of June 26 (p 1242) and your note on p 1267 on the *Scrapbook* which I had already read. We in Aberdeen are justly proud of the generous references in these places to Sir James McGrigor, and to Sir James Cantlie and his distinguished son, now our Director-General, commemorated in various ways and places—e.g., the McGrigor Mess at the Cambridge and the Cantlie Club—but I cannot help thinking that it is a serious omission to have left out all reference to our Professor Sir Alexander Ogston whose contribution to the initiation and inauguration of the R.A.M.C. is well epitomized by one of the contributors to a privately printed book on Sir Alexander Ogston when he says 'Another of his contributions that seems to be forgotten is his "bombshell" Address in Surgery at the Portsmouth Annual Meeting in 1899 of the British Medical Association, when he arraigned and impeached the Army Medical Department, an address which led undoubtedly to the high position taken by the R.A.M.C. in the Great War. Full credit does not appear to have been awarded to Ogston for this bold frontal attack, carried out in true Ogstonian fashion, but *Si monumentum requiris circumspice*. Perhaps the B.M.A.'s recent repeated chastenings have produced a sort of inferiority complex, but it is to the credit of the B.M.A. that it was at one of its Annual Meetings that this address in surgery was delivered by Prof. Alex. Ogston of Aberdeen in an address that was destined to have such far-reaching effects producing R.A.M.C. results in the two great wars second to none—I am etc,

Aberdeen

W. C. SOUTER

### Foetal Infection in Prolonged Labour

SIR—I was greatly interested in the case of neonatal *B. coli* meningitis reported in the *Journal* (June 19, p 1180) by Drs H. R. Duval and J. T. Burrowes since it draws attention to the foetal dangers of prolonged labour. However I was surprised to find no reference to the work of Douglas and Stander (1943) who studied intra-partum infection of the foetus as a cause of stillbirth. By means of blood culture from the foetal heart they discovered 83 cases of bacteraemia in foetuses stillborn after prolonged labour, and in over 50% of these cases there was histological evidence of infection spreading into the placenta from the foetal surface. The most usual infecting organism was the anaerobic streptococcus. They concluded that the commonest portal of infection into the foetus was directly through the placenta while inspiration of infected liquor into the air passages and infection through the maternal blood stream were less frequent causes. They also considered that apparently intact membranes do not constitute an impassable barrier to organisms.

Now prolonged labour is a common event, but it is relatively rare for an infant which has been delivered alive to die from infection in the first few days of life. Consequently if Douglas and Stander's results are confirmed, there must undoubtedly be many cases in which a newborn infant has an unsuspected bacteraemia and makes such a steady recovery that it is never diagnosed. In order to throw light on this point foetal blood cultures were made from cord blood in five cases of prolonged

labour delivered by caesarean section in the Birmingham Maternity Hospital, positive cultures were obtained twice (anaerobic streptococci, and *B. coli*), and both infants made normal progress.

It would therefore seem possible that infection of the foetus during prolonged labour is far more common than is generally imagined, and this might well account for the increase in rate of the foetal heart so commonly observed in these circumstances. It would also appear that neonatal immunity or resistance to infection is remarkably high—I am, etc.,

### Abortion Reform

SIR—The recent trial of two women doctors at the Old Bailey should bring home to us how an honest medical practitioner runs the risk of prosecution if he or she procures, or aids in procuring, an abortion for a woman whose life would not actually be endangered by a confinement, however dire the straits to which an unwanted pregnancy brings her. The law relating to abortion is admittedly in an unsatisfactory state.

The Lord Chief Justice, in the debate on the Criminal Justice Bill, said that if a law is bad it is his duty to administer it, but that he would do all in his power to get it altered. The Abortion Law Reform Association was founded to get the present law amended and widened, giving thereby more protection to the doctor who acts in good faith, and to lessen the terrible incidence of mortality and morbidity which results when women who have been refused help by a law-abiding doctor submit themselves to the dangers of 'back-street surgery'. The Association needs many more members so that its work of enlightening the community on the subject of abortion may be increased and necessary changes in the law brought about. The Secretary of the Association is Mrs Alice Jenkins Abortion Law Reform Association, 53, Gloucester Terrace, London, W 2, and she will gladly supply inquirers with information and literature—I am, etc.,

London S W 13

EVELYN FISHER

### Balanced-pulse Galvanism

SIR—Credit is due to Wing Commander C E G Wickham (June 12 p 1136) for his ingenuity in the design of the balanced pulse galvanic stimulator, but the elaboration of technique is not in itself an advantage, unless the basis on which it rests is well established. Although much attention has recently been given to the galvanic stimulation of denervated muscle, no evidence has yet been brought forward as to its clinical value, and there are experienced observers who believe that it is actually detrimental to recovery.

The history of a large prisoner-of-war camp in the East is significant. Among the prisoners was an eminent neurosurgeon, and a number of nerve sutures were performed by him. No electrical treatment whatever was given, for none was available. According to information obtained from a competent observer, the results were strikingly favourable. No doubt the good results were due to the skill of the surgeon but the entire absence of galvanic stimulation may reasonably be regarded as a contributory factor. A comparison between groups of cases treated and not treated by galvanism would be of great value—I am, etc.,

Sheffield

R G ABERCROMBIE

### Drug Addiction

SIR—My proposal to use, for relief of pain, as far as possible morphine suppositories instead of injections has been criticized in your annotation (Dec 13, 1947, p 965). May I add in support of my opinion that the risk of psychic habituation seems to me lessened when the patient is not aware what is given to him, while the syringe means for him in most cases "morphine". Furthermore, using suppositories, the 'needle addiction' (p 513 of my monograph) is avoided. On the other hand I agree that some danger will persist.

The proposal of Dr F R Ellis (Jan 24, p 175)—viz, to treat the addict permanently with controlled doses of the habit-

forming drug to which he is accustomed—already rejected by Dr G Laughton Scott (Feb 21, p 367)—has been experienced on a large scale in the so called "narcotic clinics" some 30 years ago in the U.S.A., with extremely bad results (see p 525 of the monograph). These "clinics" have been proved not only useless but also dangerous for the addict himself and for spreading drug addiction. A recent intention of the Mexican Government of opening such 'clinics' has fortunately been abandoned, persuaded by the competent League and American authorities. If Dr Ellis's proposal is followed, the result for the poor addict would be only a permanent change between heaven and hell, with all the very bad consequences for the patient. Furthermore, the addicts which Dr Ellis has in mind already demonstrate through the elevated doses which they use that they do not belong to the so called "benign" form, where an 'arrested development stage' can be observed, this is quite uncommon and inherent, and cannot be 'produced' artificially in addicts as Dr Ellis seems to believe—I am, etc.,

P O WOLFF

### New Conception of Angina Pectoris

SIR,—In reply to Dr Neil Gordon's letter (June 19, p 1205), in which he asked how I explain the action of nitrites in relieving anginal symptoms, I should like to make the following observations.

Nitotine is known to act on the ganglion cells of the unmyelinated fibres of the autonomic system. Pharmacologists agree however that nitrites produce vasodilatation by direct action on the walls of the arterioles, including the coronaries. They may then cause coronary vasodilatation in cases of coronary vascular disease without affecting the activity in coronary vasodilator nerve fibres. Such a vasodilatation may result in the removal of the supposed metabolites or P factor, which are thought to be responsible for initiating the excessive reflex activity in the vasodilator pain fibres passing to the coronary vessels in cases of angina due to coronary vascular disease. That this is probably the explanation of their effect is borne out by the fact that nitrites do not relieve all cases of angina pectoris, but only some of those due to coronary vascular disease. For example they had previously been tried without relief in the two cases of angina of extra cardiac origin described in my paper. Moreover, in some cases of angina due to coronary vascular disease nitrites do not relieve symptoms and because of this and the unpleasant side-effects some patients may decline to take them. Presumably in these cases the vessels are so severely sclerosed that they can no longer be dilated further. If nitrites act on the vasodilator fibres the degree of arteriosclerosis would have no effect in modifying the action of nitrites.

While nitrites are usually said to produce their effects by direct action on the blood vessels, there is some evidence that they may also act reflexly. They certainly cause a marked alteration in autonomic activity when administered to the intact animal. Nitrites act better and more rapidly when put under the tongue than when taken into the stomach, the normal pathway for absorption and passage to the heart. This suggests their effect on pain may be indirect. Lastly, there is the observation that nitrite inhalation causes a marked sensation of constriction in the chest, like that in angina, and in a number of cases has resulted in sudden death similar to that which occurs in cardiac anginal attacks. This makes it seem possible that nitrites may in fact induce anginal symptoms in certain circumstances.

The effects of nitrites were not considered in my paper, as they provided no evidence for or against the theory I put forward—I am, etc.,

## ASTHMA

*- aborting  
the night attack*

In a new paper (Practitioner, June, 1948, p. 468.9) the author attributes to 'Franol' the power of suppressing nocturnal asthmatic attacks in patients who otherwise are awakened regularly in the early hours. Under 'Franol' treatment they gain in weight and appetite and are much better fitted to lead a normal life.

The author states that, of the many preparations tested, 'Franol' gives the best results, through the actions of theophylline (on bronchial musculature), ephedrine (on nerve endings) and 'Luminal' (centrally), there is probably some potentiation since the dose of each component is small.

One tablet at night and one on rising appears to meet most needs, and by-effects are rare, the 'Luminal' in 'Franol' mitigates nervous tension and overcomes any individual intolerance to ephedrine.

## A woman with an intimate problem . .

The question of whether or not to use internally worn sanitary protection is one which all women face sooner or later. In doing so they naturally seek the guidance of one whose advice they completely trust—that of their Doctor. Tampax, which was invented by a gynaecologist and has already been accepted by thousands of members of the Medical Profession throughout the world, deserves your endorsement for its assurance of hygiene, physical comfort and alleviation of mental strain. If you are not acquainted with Tampax, descriptive literature and samples of both absorbency sizes will gladly be sent on request.

*\* Tampax may be confidently recommended by Physicians for use by married women during normal menstruation. Its use by unmarried girls should not be advocated when the size of the hymen at coitus would cause difficulty in insertion and withdrawal.*

## . . consults her Doctor

Issued by Tampax Ltd., 110 Jermin Street, London, SW 1

## The time, the place —and the Portanaest

It means much to the General Practitioner to know that the Portanaest is always at hand, equally ready for midwifery in the home and minor surgery in the consulting room or factory. Completely portable, it is very compact yet leaves nothing to be desired in the completeness of its equipment or the easy facility of its use. A master knob controls the rate of flow and pressure; another controls the mixture which can be read from the dial at a glance. For dentistry the Portanaest can best be described as a portable Walton—an indispensable part of a visiting practitioner's equipment. A demonstration will be gladly arranged. Literature is available on request.

and only 7 had been obliged to seek lighter employment, of 7 operated patients only 2 are fully capable of working. In the reference to Dr Boysen's review—some significant figures have been omitted 86.5% (225 out of 260) have complete working capacity while 30 are fit for light work. Only 5 are unable to work. These figures agree with those of Kuhns,<sup>2</sup> who found that 790 out of 1 000 patients recovered completely from sciatica without operation.

If, as Prof Jefferson emphasizes, the clinical picture of disk protrusion does not differ at all from that of the cases in which no protrusion was found at operation, it is possible that the pain is not due to the protrusion. This possibility is strengthened by the recent demonstration that complete recovery is the rule after a negative exploration of the lumbo-sacral canal.<sup>4</sup>

Most of the optimistic reports of operation on intervertebral disks are based on surveys conducted by questionnaire. We should welcome therefore, the recent appearance of two reports based upon the physical examination of the patients by practitioners who had not performed the operation: (i) Aitken and Bradford<sup>6</sup> results good in 50 out of 170 cases, 45% unable to return to work. (ii) Lenhard (reviewing the work of the late W E Dandy) only 35 out of 147 are entirely well—I am, etc.,

Melbourne

#### Termination of Pregnancy

SIR—Women desirous of having their pregnancies terminated on psychiatric grounds generally fall into one or other of the following groups: (a) the frankly neurotic, (b) those who have previously had a psychotic illness, (c) the pre-menopausal often associated with (a) or (b), (d) the unmarried, (e) the married with as many children as they can reasonably manage (inadequate housing, economic factors, etc., constitute very real problems in this group), (f) those who attempt to evade their normal and natural responsibilities on some frivolous pretext. The syndromes presented by each group are fairly constant for that group. Each case should be decided on its merits, and it is important to obtain as much corroborative evidence as possible before reaching a decision, which as Dr Chessier so aptly puts it (June 5, p 1110), is 'practically always a choice between a greater and a lesser evil'.

Childbirth is the natural function of women, and any reluctance on a woman's part to carry on with a pregnancy must be viewed with concern. We should not think merely in terms of a condition reactive to an unwanted pregnancy. If we do so we may fail to identify a deep-seated disorder, which may involve the patient in a mental breakdown whether her pregnancy is terminated or not. The most difficult cases to assess are the unmarried women with stable past histories. The social and economic consequences of having an illegitimate child obviously have more violent repercussions upon them, by and large, than does the advent of an unwanted child to a married woman. The unmarried unwillingly pregnant woman frequently commits suicide while her married contemporary rarely does so.

As previously mentioned the acute disturbance precipitated by an unwanted pregnancy may readily obscure a serious disorder of personality. The relief afforded by a therapeutic abortion tends to produce a false sense of security in such cases. Before reaching a decision, therefore, on the desirability of terminating a pregnancy, a comprehensive psychiatric investigation is called for preferably spread over a number of interviews. It has been difficult in the past to insist on further treatment after the surgical interference has been concluded but with the advent of the National Health Service psychiatric treatment should be available to patients who formerly could ill afford it. Psychological treatment is as important after therapeutic abortion on psychiatric grounds as is the re-education and rehabilitation of a patient after amputation—I am, etc.

London W 1

ELLIS STUNGO

#### Staff Test for Nurses

SIR—In connexion with the current discussion on the training of nurses I should like to draw attention to certain questions in the fevers paper recently set for the Final State Examination of the General Nursing Council:

1 'Which infectious diseases may be complicated by involvement of the central nervous system, what are the special risks and how may the diagnosis be confirmed?'

2 'Describe the appearance, cultural characteristics, and properties of the diphtheria bacillus.'

Apart from the scope ambiguity, and complexity of the first question there arises an important point of definition. In regard to the second question an adequate answer would involve a knowledge of bacteriology quite beyond that which should be required from student nurses. In fact the Council's syllabus merely refers to the 'causation of diphtheria and a standard textbook in popular use among nurses deals with the subject in a few lines.

Questions such as these produce a sense of frustration and not unreasonable indignation among candidates. As one responsible for the training and recruitment of nurses I suggest that the requirement of such academic standards of medical and bacteriological knowledge does not tend to produce or discover good practical nurses, nor does it help to overcome existing difficulties in regard to nursing shortage and lack of recruits to the profession—I am, etc.,

Ilford

J H WEIR

#### Convalescent Homes

SIR—We see all round us the deplorable results of sectionalism both at home and in the international field. In a small way we may combat this evil by taking care that it is not made part of medical planning. I have been struck by the opportunities presented when patients are sent away to convalesce.

Recovery is inevitably assisted by stimulating surroundings and contacts. It is therefore regrettable that in so many places convalescents are collected from one small occupational group whereas if persons in a variety of different employments were brought together they would from the very diversity of their interests stimulate one another while broadening their minds. In this way some little may also be done to remove those distrusts and animosities which derive from a narrow and restricted way of life. For these reasons it appears desirable to make the most of an opportunity to secure on the same occasion a more rapid physical and mental recovery with, as one may hope, an increase in social and political sense—I am, etc.

Hadley Woods Herts

G C PLTHER

#### Short Leg in Soldiers

SIR—We read with interest Dr Nesta H Wells's letter (June 19, p 1206) on scoliosis in school children and her plea for early compensation for leg shortening by heel raising. In dealing with recruits in the Army who are sent to the Army Physical Development Centre we have found a high incidence of leg shortening with resultant scoliosis. The recruits sent here are mostly in the 17½–18½-years age group. The shortening varies from 1/4 in to 1½ in (0.63 cm to 3.7 cm). Remarkably few give any history of backache sciatica or bone injury to the lower limbs, or of poliomyelitis. Even fewer are aware prior to our examination that there is any shortening.

It is our practice, however, whether symptoms are present or not, to compensate for shortening by heel raising as a prophylactic measure against back pain, except where the shortening is 1/4 in or less. Such shortening we regard as a normal variation. In all cases where symptoms are present, and especially in youths of this age group it is most important that other causes of low back pain, including ankylosing spondylitis are ruled out. We therefore make it a rule in these cases to have an x-ray examination of the spine and sacro-iliac joints.

Shortening of between 1/2 in and 1/4 in we treat by raising the heel on the affected side by that amount. Heel raising of more than 1/2 in gives rise to a somewhat cumbersome boot. Therefore when the shortening is of more than 1/2 in we find

more satisfactory to raise the heel on the affected side by half the required amount and to lower the heel on the opposite side by a corresponding amount. We have found that few of these young soldiers feel any awkwardness or discomfort from boots altered in this manner, in fact most of them say that they now feel more comfortable. When the boots have been satisfactorily adapted we impress upon these youths the desirability of maintaining these alterations throughout their service and on return to civilian life.

We are deliberately omitting any statistics as we feel that the recruits sent here are not a true cross-section of young adults, since they are specially chosen to attend a remedial course for various postural or other defects at this physical development centre—We are, etc.,

### The SRM

SIR,—In the interests of accuracy may I point out that the principal point of Dr Holman's letter under the above heading is founded on a mishearing or misconception? The proposal duly seconded, from the body of the Great Hall and accepted by the Chairman, and approved by vote of the majority by a show of hands was "that the meeting pass to the next business." In a short subsequent discussion, from the body of the Hall, this was agreed as intending to pass by all the motions of censure on the Council—but not those applying to censure of the Editor of the *Journal*. The first of the motions referring to the Editor was moved, spoken to by several speakers and rejected by a huge majority. Of course I do not know what the Chairman said to Dr Holman on the platform but this was the actual sequence of events, my memory of which is perfectly clear.

In taking the action he did the Chairman was merely conforming to the wishes expressed by vote of the majority of the Representative Body—I am, etc.,

Plymouth

CYRIL F MAYNE

### Remuneration of General Practitioners

SIR—A leading article in *The Times* of May 15 comments on the Spens report with special reference to the remuneration of dentists, but the case of the general medical practitioner demands equal consideration. Since the Minister announced his terms of service last December general attention has been concentrated upon matters of principle, and the actual payment of doctors was not an issue in either plebiscite this year. Now that the B M A has recommended the profession not to refuse co-operation in the Service the amount of remuneration becomes of immediate importance.

It should surely be conceded that acceptance of service under the Act ought not to involve a loss of income for the rank and file of the profession. But careful study of the Minister's proposals shows that grave financial loss may be caused to a high proportion of doctors who have hitherto owned mixed "panel" and private practices. It is becoming increasingly obvious that, owing to the high compulsory National Insurance contributions and the heavy charge on income tax receipts to maintain the Health Service, most patients will feel unable to pay doctors bills in addition so the amount of private practice remaining will generally be very small, and in most mixed practices the future income from this source will be negligible. Salaried appointments, such as district medical officers for public assistance and public vaccinators, will terminate, since all patients are to be placed on doctors' lists and compulsory vaccination ceases. The vast majority of general practitioners are thus likely to be almost entirely dependent upon capitation payments for National Health Service patients, and this being so the proposed capitation fee should be much increased. It must be remembered that the Spens recommendations were based on the pre-war cost of living and that their investigations were into the income and expenses of doctors during the years 1936-7-8. Since then every essential item of a doctor's professional expenses has greatly increased—sometimes (e.g. cars) by 100%.

Two methods proposed for calculating fees are unjust (1) The fewer the patients joining the Service the higher the

capitation fee (15s 2d for 95% increasing to 18s for 80%, of the population). This should be reversed, since the fewer there are in the Service the greater the potential income from private practice, and *vice versa*. (2) A central fund is proposed equal to a capitation fee of 18s multiplied by 95% of the population. The first charges on it would be payment for mileage, temporary residents, emergencies, etc., and "inducements" or basic salaries. What is left becomes the general capitation fee. It would be better to settle a firm capitation fee first and pay other charges from a separate fund after.

The disastrous effects of the present proposals on doctors in a typical rural area can be shown by one concrete example. In a certain district of 9 parishes there is a population of 10,000 of whom 7,500 are concentrated in two adjoining villages. With the gross capitation fee of 18s the income payable to doctors practising here would be £9,000 but with the more likely actual fee of about 15s it would be £7,500. There are 10 general practitioners in this district, of whom 8 have mixed panel and private practices. If practice expenses are taken at 25%, the net income these doctors may expect would be £5,625 for a 15s capitation fee rising to £6,750 for one of 18s. Even if one were justified in assuming that only 8 of these men were fully occupied, none of them could hope to earn as much as £1,000 per annum. In none of these practices does the income received from present panel capitation fees amount to a quarter of the gross receipts, so the losses may thus amount to 50% of their present income. (The lower figure cannot allow for mileage payments, but the 18s proposed by the Minister probably more than covers what may at present be expected.) This very disturbing example of the general practitioner's prospects could doubtless be multiplied throughout the country.

The changes by voting shown in the last plebiscite were undoubtedly prompted by economic pressure, but of those general practitioners voting 67% still disapprove of the Act and 53% were against accepting service. It is obvious that most of the profession will enter the Service with grave misgiving and the prospect of a serious drop in income and standard of living. The Service must inevitably cause harder work for doctors. It offers no payment for locums—the doctor must "provide a deputy"—and no lessening of hours during which a man is liable for duty. When in every other walk of life higher wages are being paid for shorter hours, is it fair that doctors should receive so much less for more work, and under conditions of service which are still distasteful to so many?—I am, etc.,

RALPH GREEN

### Medical Education and the G P

SIR—Two committees have now recorded their recommendations for the reform of medical education. The latest report states that "the undergraduate curriculum can do no more than lay the foundation of a doctor's education but it should stimulate him to remain a student all his life" (*Journal* May 29, p 1038). How, in the face of all the clerical work he must perform, can a G P remain a student? I have heard of practices where the dispenser divides the waiting-room patients into (a) those wanting certificates, (b) those asking for medicine, and (c) those demanding letters to visit the hospital "to be examined." How is this to be prevented when there is so great a temptation to allow it to spread under the NHS? The committee on postgraduate education which is to be set up may be able to tell us.

I would like to make the following suggestions:

(1) We attempt to divide the work so that the numbers of NHS patients are between 1,500 and 3,000 per doctor.

(2) We try to maintain the clinical enthusiasm instilled in us by our specialist teachers. What G P can deny that feeling of satisfaction at detecting for example, a patch of bronchial breathing in a feverish patient with pain in the chest?

(3) We give ourselves time to examine our patients and make at least a tentative diagnosis for all patients referred to a specialist. Surely this, if only from the mistakes we make, is how we shall learn. We may also help to cut down unnecessary investigations, the rising flood of which Dr Ffrangcon Roberts justly deplores (March 13, p 485). I like the story (told by one of my recent chiefs) of the Regular Army specialist replying to a brief, "Please examine and advise," with, "You examine and I will advise."

2. (1) Private certificate may be accepted by the National Insurance (2) Private patient not be charged for obtaining and free of charge in the N.F.S.—En. E.M.

## Medico-Legal

### COMPENSATION BARRED BY UNSKILFUL TREATMENT

[FROM OUR MEDICO LEGAL CORRESPONDENT]

If a workman is injured at work and unskilfully treated, it appears that his disability may be held to result from the treatment and not the accident, so that he may be refused compensation. As Lord Justice du Parcq said in 1941, negligent or inefficient treatment by a doctor or other person may amount to a new cause, a *novus actus interveniens* shifting the liability from the employer. The courts are always anxious to interpret the Acts beneficially to the worker, and the Court of Appeal in a recent case<sup>1</sup> strongly criticized this doctrine and hoped the House of Lords would deal with the matter, but were unable to upset it as it has been supported by several earlier decisions of the court, which by custom and law are binding.

The workman in this case had an unusual deformity—a small supernumerary thumb. This was injured by a flying stone. After conservative treatment he was put on light work but the pain remained and the doctor at the emergency hospital advised the removal of the supernumerary and also of the upper part of the normal thumb beside which it lay. This was done but the stump, in consequence of the operation, remained sore and disabled the man. The county court judge held that the disability was due to the ill advised operation. The Master of the Rolls Lord Greene, recalled that the doctrine of a new intervening cause in such cases came from early in the history of workmen's compensation when courts were more concerned to protect the employer, or at any rate less tender to the workman. He thought the correct view should be that an incapacity caused immediately by unskilful treatment might in truth be due to the accident and attributed to it, provided that recourse to the treatment was the natural and reasonable consequence of the accident. Nevertheless the court was bound to follow the law as it stood, and the judge's decision, which was supported by evidence, could not be interfered with.

Worth noting is his remark that he would have thought that one of the earlier cases, in which the workman went to a bonesetter would have been decided on the simple ground that to go to a bonesetter instead of to a proper medical man was in itself unreasonable.

## Medical Notes in Parliament

### NATIONAL HEALTH SERVICE

#### Public and Private Practice

Miss ALICE BACON inquired on June 24 under what authority a doctor refused to take a person on his list and intimated that he was prepared to take the same person as a paying patient.

Mr BEVAN said such conduct was quite unethical. He confidently expected that the profession would express the strongest disapproval of it.

Miss BACON said this conduct occurred and gave point to the contentions advanced by some Labour Members during the Second Reading of the National Health Bill that to allow a doctor in a public practice also to undertake private practice was a means whereby public confidence in the whole scheme could be destroyed.

Mr BEVAN hoped that as experience was gained this practice would disappear. It was believed in only by a very small proportion of the medical profession. It ought to receive the disapproval of the House and the country.

Mr WILSON HARRIS asked whether there was a specific remedy when a doctor refused to take a patient on the ground that the patient was in a position to pay and therefore was not accepted on the general list.

Mr BEVAN said such patients could go to another doctor. If at the end of the process they were without a doctor they could be assigned to one. There had been one or two cases where a doctor had taken a husband and wife and had refused to take the children. He believed that this also was frowned on by the medical profession.

Dr SEGAL asked Mr BEVAN to enlist the active co-operation of patients in reporting such instances.

Mr BEVAN replied that the patients were obviously making their complaints known or else the House would not have heard about them.

#### Supply of Drugs

Mr RANDALL asked the Minister of Health how many instances of doctors informing their patients that there was a restriction on drugs which could be ordered for free supply for the proper treatment of patients under the new Health Service had been brought to his attention, what steps he had taken in the matter, and what action was open to patients so informed by their doctors. A similar question was put by Mrs LEAH MANNING.

Mr BEVAN said he trusted there had not been many such cases. He was confident that doctors would not attempt to discriminate between those who used the Service and those who did not. He welcomed this opportunity to make it clear that patients were entitled under the new Health Service with out restriction to every kind of drug and appliance necessary for their treatment. Any doctor who failed to prescribe these drugs would be breaking his terms of service. He hoped this statement would receive the widest possible publicity. When a doctor made the statement which Mr Randall had cited the course open to the patient was to make a complaint to the local Executive Council. That council would investigate the complaint. There was machinery under the Act, to deal with the matter. All he himself could do was to call attention to the facts and ask the public to note what was said in Parliament and not to listen to what certain doctors, who had acted well below the ethical standards of the profession, had said.

Col STODDART-SCOTT asked for an assurance that doctors would not be surcharged for supplying certain drugs, as they now were under the panel system.

Mr BEVAN said there were regulations which concerned themselves with the nature of the drugs to be prescribed. Certain things were prescribed as drugs which were not drugs—champagne, for example.

#### B.M.A. Co-operation

Dr HADEN GUEST asked whether Mr BEVAN knew that the British Medical Association took the strongest view of the improper conduct which a few doctors had followed and was taking action to bring this to the attention of the whole profession. He asked further whether Mr BEVAN did not agree that, since the B.M.A. was co-operating to give the best possible service under the slogan of Dr Dain that 'Only the best is good enough,' it was desirable that its help in this matter should be welcomed by the Minister.

Mr BEVAN replied that he had already welcomed the help given by Dr Dain especially in a letter written recently to *The Times* (June 18). Mr BEVAN was happy that the vast majority of the medical profession frowned on the practices which had been brought into question.

#### Maternity Services

Mr HASTINGS asked Mr BEVAN why he had decided to reverse the policy of Statutory Instrument 506 as regards the method of obtaining maternity medical services by encouraging doctors who had no midwifery experience to undertake maternity work and arranging to pay them for it.

Mr BEVAN said he had decided after consultation with the medical profession to provide a lower fee for maternity medical services undertaken for his own patients by a doctor with ordinary experience. Such a doctor could not otherwise receive any fee for such services, either from public funds or from the patient. This did not affect the higher fees for special experience or the main objective that maternity work should generally be done by practitioners with such special experience. A general practitioner could do obstetrical work now and did so, so no new scandal was being created. A new system was being introduced which would mitigate the present evils. He hoped before long the system would entirely remove them. The scheme was to create a panel of general practitioners who would do obstetrical work and relieve other general practitioners without the same experience from doing it. This would powerfully modify and improve the existing practice. A doctor would be paid for obstetrical work if he did the work for his own patient at that patient's request.

#### Temporary Residents at Holiday Resorts

Sir ERNEST GRAHAM-LITTLE asked on June 25 whether the Minister of Health would make arrangements to meet the difficulty of medical practitioners at holiday centres, where the population was increased at certain times of the year but the practitioner's capitation fee was to be based on patients

from the permanent population, with a consequent loss to the practitioner during the holiday months.

Mr BEVAN answered that the arrangements for paying doctors for attendance on temporary residents which would be simplified under the new scheme, would meet this difficulty.

#### Transfer of Officers and Compensation

On the motion of Mr JOHN EDWARDS, the House of Commons on June 23 approved without debate the draft National Health Service (Superannuation) (Amendment) Regulations 1948. Mr Edwards then moved that the House approve the draft National Health Service (Transfer of Officers and Compensation) Regulations, 1948.

Mr BURDEN said he was disappointed that the Minister took power to depart from the accepted code of compensation applicable to the Local Government Service. This code, which resulted from negotiations between the National Association of Local Government Officers and the Ministry of Health, was being definitely worsened. The Minister was breaking a pledge given by the Minister of National Insurance when the National Insurance Bill was under discussion. That Minister then said that when the State transferred functions it accepted liability for absorption or compensation of staff.

The DEPUTY SPEAKER suggested that the corresponding regulations relating to Scotland should be discussed at the same time. This was agreed.

Commander GALBRAITH said the regulations laid down that a claimant must have served eight years to be eligible for consideration. Why was that period chosen?

Mr CARMICHAEL said the Glasgow Authority had decided to have a full-time medical service under the Poor Law. The entire duties of the medical people in that service were confined to the aged and sick who were on the Poor Law. A number of them had been advised by the Glasgow Authority that there was no employment for them under the Regional Hospital Scheme and none under the Scottish Office. Some of them had at least ten years service, and for them to enter ordinary medical practice was not an easy task. Should these medical officers or other local authority officers make an effort to be self-employed and soon discover that they were incapable of so continuing, what would be their position in regard to compensation?

Mr EDWARDS said the new code was the result of careful consideration in the light of present circumstances. This code would apply to all transfers which followed upon current legislation. The Ministry would do everything it could to ensure that claims did not arise but he stressed the point that there was a great shortage of manpower in this field. The Minister would be no less humane than local authorities had been in the past and the door of the Ministry would always be open to the Association of Municipal Employees. The eight-year period was in the nature of a compromise. The provision of two-thirds of the old salary as the maximum compensation was taken from the old Local Government Code. How close one went to the maximum would depend on the length of service. In the matter of comparable employment the Government would do its best so to arrange transfers and to offer employment that there should be the minimum of inconvenience and trouble to the person concerned. The Government had felt it ought to increase the amount of extra compensation because of years of age and had so provided for those over 45—because what seemed important was the age of a person rather than the actual years spent in the service. In regard to the provision that no compensation was payable for a diminution of emoluments less than 5% even on large salaries these amounts were negligible when allowance was made for income tax.

Mr RANKIN asked whether in the case of an officer transferred to another district the Department would pay him for his accommodation while in his new position? Mr EDWARDS said that matter ought to be discussed between the Associations and the Department in considering conditions of service.

The Draft Regulations for England and Scotland which had been under discussion were then approved.

#### Superannuation Regulations

Mr EDWARDS then moved that the draft National Health Service (Superannuation) (England and Scotland) Regulations, 1948 be approved.

Col GOMME-DUNCAN asked whether the provision for cross-posting from England to Scotland and from Scotland to England portended that a large scale transfer was likely to be made under the new Health Service. Mr FRASER did not expect that there would be any large-scale transfer, but said that as usual there would be more transfers from Scotland than to Scotland.

The House then agreed to the regulations. Approval was also given to the draft National Health Service (Scotland)

(Superannuation) (Amendment) Regulations 1948, and to the draft National Health Service (Transfer of Officers and Compensation) (Scotland) Regulations, 1948.

#### VENEREAL DISEASE

LORD BALFOUR OF BURLEIGH in the House of Lords on June 29, asked the nature of the difficulty in administering the VD Acts and Regulations which led to the withdrawal of the statutory protection of secrecy from persons receiving treatment at VD clinics and whether it was contemplated that in future information as to attendance or non-attendance at VD clinics, or factual information as to the state of health of persons receiving treatment would in any circumstances be able to be communicated to the police by the medical officer of health or by a member of the VD services. He asked the number of cases in which compulsory medical examination took place under Regulation 33B now repealed and the number of cases (men and women separately) in which the persons examined were found to be suffering from venereal disease.

LORD LISTOWEL said the withdrawal of the provision resulted from the revoking of the Public Health (Venereal Diseases) Regulations of 1916. These regulations placed upon local authorities the responsibility for the treatment of venereal diseases and had been revoked because that responsibility now devolved upon Regional Hospital Boards under the National Health Service Act. It no longer appeared necessary to continue special statutory provision to the effect that treatment for venereal diseases should be regarded as confidential. The maintenance of secrecy did not primarily depend for its force on any statutory provision but rather on the proper and normal relationship between doctor and patient. There was no reason whatever to apprehend that the confidential nature of venereal disease treatment would not continue to be as closely preserved as it always had been. The number of cases in which compulsory medical examination took place under Regulation 33B was 13 men and 116 women. Information about how many of these were found to have venereal disease was not available.

#### R A F Conference

On June 28 Sir ERNEST GRAHAM-LITTLE asked the Secretary of State for Air whether he knew that at a conference of AOCs held in November, 1947, at an R A F unit in Germany, attended by all doctors, pilots and commanding officers of the wing M O's were reminded that a long-standing regulation required them to divulge to the commanding officer the names and full medical details of patients under their professional care suffering from venereal disease, these records being accessible to other persons than the CO that as these requirements constituted a breach of the obligation binding members of the medical profession not to divulge to third persons information received in their professional capacity, several medical officers present at the conference expressed reluctance to obey the regulation and if he would consider its withdrawal.

Mr ARTHUR HENDERSON replied that the officers who attended this conference were reminded of a King's Regulation which required a daily sick return showing the diagnosis and disposal of each case to be made to the commanding officer. At the conference some misgivings were expressed about the regulation, which was, however necessary to enable a commanding officer to carry out his duties in regard to the health and welfare of his unit. The situation in the R A F was not analogous with that in civil life. A commanding officer was responsible for the health of his men and for reducing the risk of infection. He must therefore be made aware of cases of venereal disease in his unit. Mr Henderson said that in these circumstances he could not agree with Sir Ernest that this regulation should be withdrawn.

**Limbless Ex-Servicemen**—Replying to Col LITTON on June 21 Mr BLEAKINSOP said that ex-Service paraplegic cases were a small group. Some 600 men and women from the last war suffered from this spinal disease and 200 were still in hospital. Of the remaining 400 patients 70% were in full and regular employment. The bulk of the treatment work for paraplegics was done at the well equipped hospital at Stoke Mandeville and two auxiliary centres at Eastbourne and at the Star and Garter Home. He hoped that by the end of the year a new hostel at Osterley Park would be available for paraplegic cases who were training for practical jobs.

**Barley Sugar**—Dr SUMMERSKILL stated that there are ample supplies of glucose barley sugar available to meet all demands against medical prescriptions, although it may not always be possible to meet the demand for the product of a particular manufacturer.

**Nutrition of School children**—Mr TOMLINSON circulated on July 1 this summary of the assessment of nutrition of school children seen at routine medical inspections in England and Wales in 1939 and 1946

Year	Number Examined	Percentages			
		A (Excellent nutrition)	B (Normal nutrition)	C (Slightly sub normal nutrition)	D (Bad nutrition)
1939 (only first two terms)	1,098 367	14.7	73.8	11.0	0.5
1946	1,563 015	16.8	75.1	7.9	0.2

NOTE (1) The figures for 1939 relate to Elementary School children and the for 1946 to children attending maintained Primary and Secondary Schools

(2) Further information on the nutrition of school children is to be found in Chapter I of the Report of the Chief Medical Officer of the Ministry of Education for the Years 1939-45

**Salaries of Deputy MOHs**—On June 29 Sir ERNEST GRAHAM-LITTLE asked the Minister of Health whether Deputy County and Deputy County Borough Medical Officers of Health commonly received a salary of between £800 and £900 per annum, whereas specialists under the Spens Committee Report are to receive a commencing salary of £1,500 linked to age 32 years. Sir Ernest asked him to grant the above officers classification and remuneration as specialists when their status and qualifications were equivalent to those of officers recognized as specialists in other branches of the National Health Service.

Mr BEVAN replied that it was not for him arbitrarily to determine these officers' salaries, but rather to encourage appropriate negotiating machinery for dealing with any proposals for revision.

## EPIDEMIOLOGICAL NOTES

### Discussion of Table

In *England and Wales* infectious diseases were less prevalent during the week, and the decreases included measles 1,601, whooping cough 212, and scarlet fever 20.

Alternate rises and falls have been a feature of the returns of measles during the past three months. During the week the largest decreases in the notifications of measles were London 328, Essex 311, Warwickshire 283, Durham 208, Middlesex 192, and Kent 102. The counties with an increased incidence of measles included Derbyshire 69, Northumberland 51, Devonshire 42, Lincolnshire 42, and Monmouthshire 42.

Only a few counties recorded large fluctuations in the trends of whooping cough. The largest decreases were Middlesex 76, Nottinghamshire 53, Gloucestershire 52, and Essex 48, while in the combined area of London and the south eastern counties a rise of 72 was recorded. No changes of any size were reported in the local returns of diphtheria. Only small variations occurred in the local incidence of scarlet fever. In the south eastern, south-western, and northern counties there was a tendency for a small increase and in the remainder of the country the incidence either decreased slightly or remained constant.

The largest returns of dysentery were Yorkshire West Riding 24 (Bradford CB 10, Aireborough UD 11), London 16, and Lancashire 10. Lancashire with 5 notifications of acute poliomyelitis was the only county with more than one notification of this disease.

In *Scotland* increases occurred in the notifications of scarlet fever 81, acute primary pneumonia 11, and diphtheria 9. Decreases were reported for measles 63 and cerebrospinal fever 10. The rise in the incidence of scarlet fever was due to an outbreak in the county of Lanarkshire, where 101 cases were notified during the week. The notifications of diphtheria in Glasgow were 11 more than in the preceding week.

In *Eire* infectious diseases were slightly more prevalent, and the rises included measles 26 and whooping-cough 25. The largest of the local outbreaks during the week were 24 cases of whooping cough in Kilkenny Kilkenny RD, and 17 cases of measles in Galway Loughrea RD.

In *Northern Ireland* only small changes were reported in the trends of infectious diseases.

### Week Ending June 26

The notifications of infectious diseases in *England and Wales* during the week included scarlet fever 1,649, whooping cough 2,803, diphtheria 137, measles 10,571, acute pneumonia 373, cerebrospinal fever 34, acute poliomyelitis 27, dysentery 64, paratyphoid 8, and typhoid 3.

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended June 19.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year for (a) *England and Wales* (London included) (b) *London* (administrative county) (c) *Scotland* (d) *Eire* (e) *Northern Ireland*. Figures of Births and Deaths and of Deaths recorded under each infectious disease are for (a) The 126 great towns in *England and Wales* (including London) (b) *London* (administrative county) (c) The 16 principal towns in *Scotland* (d) The 13 principal towns in *Eire* (e) The 10 principal towns in *Northern Ireland*. A dash — denotes no cases a blank space denotes disease not notifiable or no return available.

Disease	1948					1947 (Corresponding Week)				
	(a)	(b)	(c)	(d)	(e)	(a)	(b)	(c)	(d)	(e)

Deaths (0-1 year) Infant mortality rate (per 1 000 live births)	295	32	35	14	14	420	38	73	25	15
Deaths (excluding still births) Annual death rate (per 1 000 persons living)	4,178	635	536	186	109	4,089	626	583	192	111
Live births Annual rate per 1 000 persons living	8 565	1412	1074	434	264	9,630	1499	1225	498	304
Stillbirths Rate per 1 000 total births (including stillborn)	211	16	32	—	—	258	25	32	—	—

\* Measles and whooping cough are not notifiable in *Scotland* and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for *England and Wales* (London (administrative county)) will no longer be published.

‡ Includes primary form for *England and Wales*, *London* (administrative county) and *Northern Ireland*.

§ The number of deaths from poliomyelitis and poliomyelitis for *England and Wales* (London (administrative county)), are combined.

|| Includes puerperal fever for *England and Wales* and *Eire*.

## Medical News

### Viscount Addison

The Rt Hon Viscount Addison, K G, P C, M D F R C S, has been appointed Paymaster-General in succession to Mr H A Marquand, M P, who becomes Minister of Pensions in place of the Rt Hon George Buchanan, M P, appointed Chairman of the National Assistance Board. Viscount Addison will hold the office of Paymaster General with that of Lord Privy Seal.

### Entered Health Service

The Ministry of Health and the Department of Health for Scotland have announced that the number of doctors in Great Britain who had enrolled under the National Health Service was 18,514 up to Saturday, June 26. This figure was made up of 1,976 doctors in Scotland (compared with 1,810 a week earlier) and 16,538 doctors in England and Wales (compared with 14,784 a week earlier). By the same date 8,131,166 applications had been received for entry on the lists of doctors taking part in the Service. The total for Scotland was 731,166, and that for England and Wales was 7,403,000. These totals do not include the 22,000,000 persons at present on the lists of insurance doctors.

### New President and Honorary Fellows of R S M

At the Annual Meeting of Fellows of the Royal Society of Medicine on July 6, with the President in the Chair, the following were elected Honorary Fellows: Field-Marshal Smuts, Sir Archibald Gray, Prof Charles Singer, Sir Henry Tidy, Prof Georges Debasieux, of Louvain, Dr Mathew Makkas, of Athens. Sir Henry Dale, O.M., has been elected President of the Royal Society of Medicine for the coming year.

### Society for Relief of Widows and Orphans of Medical Men

The annual general meeting of the Society for Relief of Widows and Orphans of Medical Men was held at 11, Chandos Street, London, W, on June 2, with the president, Sir Robert A Young, in the chair. The annual report and accounts for 1947 were received and approved and new officers for 1948-9 were elected. Income exceeded expenditure by £688. The membership of the society at the end of 1947 was 261. During the year seven widows died, one of these had received £3,793 in grants to herself and to her children. The total sum distributed in grants during the year was £4,502 10s. Widows over 65 years of age received £75, and those under 65 received £60, and at Christmas presents of £20 were made to each widow. The president referred with regret to the death on May 13, of Dr E J Blackett. At the 1947 annual general meeting Dr Blackett resigned from the office of secretary of the society, after having held the post for 42 years. Details of the society may be obtained from the secretary at 11 Chandos Street, London, W1.

### Called to the Bar

M Markowe, M D, D.P.H. (Lincoln's Inn), M G L Lucas, M B Ch B (Middle Temple), and F I McD Paterson, M B, B S, were called to the Bar on June 9.

### Scientific Information Conference

Speaking at the opening session of the Royal Society Scientific Information Conference called to examine the possibility of improving existing methods of collecting, indexing, and distributing scientific literature, Sir Edward Appleton, F R S, said that science had been well served in the past by the publications of its learned societies and academics and by the scientific journals. But the spate of scientific publications was now such that it was becoming extremely difficult to keep abreast with events on even the most limited sector of the scientific frontier. Something must be done to relieve the situation. The really important objectives to be achieved were threefold: first, to ensure that the scientist got all he needed, secondly, that he got it quickly, and, thirdly, that he got it in the right form and shape. Any solution must be practicable, it must be reasonable in cost, and it must take into account the acute shortage of scientific manpower hampering the development of almost every scientific organization in the world—and certainly every organization in the British Commonwealth. The Conference must keep constantly in mind the needs of the scientific user. 'Personally what I require, as a working scientist, are reprints or separates of the papers that matter to me, and I want them quickly and in a form easily storable. In choosing the reprints of the papers I require I want the guidance of brief abstracts to inform me of the existence and contents of those papers.' Then there was the question of translations. Here was certainly a field where co-operation would lead to economy of effort.

### Croydon Welsh Society

Mr R Glyn Thomas, F R C S Ed, has been elected the first president of the newly formed Croydon Welsh Society.

### New Chairs of Pathology

The University of London has established two Chairs in the Department of Pathology at King's College Hospital Medical School. They are the Chair of Morbid Anatomy, to which Dr H A Magnus has been appointed and the Chair of Chemical Pathology, to which Dr C H Gray has been appointed.

### William Hyde Award

The Research Board for the Correlation of Medical Science and Physical Education (Apothecaries Hall, Black Friars Lane, Queen Victoria Street, London, E C 4) announces that the William Hyde Award for 1947 has been made to Dr L G C Pugh in recognition of his work on rheumatism. The Award is named after Alderman William Hyde, who died in April, 1945. He was a trustee of the Nuffield Provincial Hospitals Trust and spent a great part of his life in helping the advancement of the health and hospital services of the country. Starting as secretary of a rural friendly society, he soon became interested in the wider problems of public health. He was an able chairman of the public health and public assistance committees of the Oxfordshire County Council and in 1935 was chairman of the Ministry of Health's Consultative Council on National Health Insurance. It was to a large extent Alderman Hyde's concern for the future of the hospital services of the country which led to the establishment of the Nuffield Provincial Hospitals Trust.

### Research Committee of Tuberculosis Association

In 1947 the Tuberculosis Association decided to set up a committee to help co-ordinate research into problems connected with tuberculosis in England, Wales, and Northern Ireland. The body now in being consists of members who are authorities in their special fields, and it is under the chairmanship of Dr F R G Heaf, President of the Association. It includes an observer from the Ministry of Health and representatives of the Joint Tuberculosis Council and the Tuberculosis Society of Scotland. There will be close liaison with a special subcommittee of the last. Other functions of the Committee will be to supply, when required, advice on the conduct of larger investigations contemplated by official bodies and manufacturing industries, to draw up schemes for adequate trials of newer methods of treatment, and to suggest to individuals and groups of individuals outstanding problems which they might usefully explore. The full Committee will meet several times a year, and there is a standing Working Subcommittee to consider problems as they arise. Communications should be sent to Tuberculosis Association Research Committee, Manson House, 26 Portland Place, London, W 1.

### John S Owens Prize

The John S Owens Prize of the Royal Sanitary Institute was offered for essays on either atmospheric pollution or the ventilation of dwellings and its effect upon human health. There were six entries for the competition, and the Council of the Institute have awarded the prize of £25 to R E O Williams, M.D., for his essay on the second of these subjects.

### Vaccination and Immunization

Local authorities will make arrangements under the National Health Service for medical practitioners to carry out vaccination against smallpox and immunization against diphtheria. The fees to be paid are being negotiated with representatives of the profession and had not been settled by the appointed day. The Minister of Health has therefore sent a letter to local authorities asking them to proceed with the arrangements and to tell practitioners that their fees will be paid as from July 5 according to the scale finally settled.

### District Nurses and Midwives

The Minister of Health has reviewed the arrangements for training domiciliary midwives and district nurses. Many of these are trained by voluntary organizations and the Minister therefore asks local authorities to ensure that existing organizations are enabled financially to continue training on the present scale after July 5.

### Sister Tutors

In view of the serious shortage of qualified sister tutors and male tutors of nurses, particularly in mental hospitals and mental deficiency institutions, the Minister has decided to increase the number of scholarships open to candidates this year from 50 to 75. Of these, 25 will be reserved for those who are prepared to give at least two years' service as tutors in mental hospitals or mental deficiency institutions. Nurses who wish to apply under this scheme should write to the Secretary, Ministry of Health, Division 3c, Whitehall, London, S W 1, not later than July 31.

## Scientific Liaison

In order to facilitate scientific co-operation within the Commonwealth the British Commonwealth of Nations Scientific Liaison Offices (London) have been opened on the third floor of Africa House, Kingsway WC2.

## Wills

Mr John William Geary Grant, who was consulting surgeon to the Royal Infirmary, Cardiff, left £4,586 5s 8d. Dr Francis Johnston, formerly of Birkenhead, left £24,785. Dr Helen Winifred Duncan of Southport, left £12,420, and Dr Vincent Sutherland Hodson, formerly consulting physician to the London Chest Hospital, left £4,911.

## COMING EVENTS

## Ethiopian Exhibition

The Ethiopian Exhibition of Arts, Crafts, and Industries will be held on July 12-17 at the Co-operative Wholesale Society's Boot and Shoe Show Room 99, Leman Street, London, E1. Traditional dress, leather work, jewellery, illuminated books, etc. will be shown, and there will be a film about Ethiopia. A box will be provided for donations to the Princess Tsahai Memorial Hospital Fund.

## Society of Chemical Industry

The annual general meeting of the Society of Chemical Industry will be held at Edinburgh on Wednesday, Thursday, and Friday, July 14, 15, and 16. The second Lister Memorial Lecture will be delivered by Sir Robert Robinson, F.R.S., on July 15, at 10 a.m. His subject is 'The Device of Imitation of Molecules in the Biological Field'.

## Vision Light and Seeing

Dr Matthew Luckiesh, director of the Lighting Research Laboratory, G.E.C., Cleveland, U.S.A., will read a paper on 'Factors Concerned in Vision, Light, and Seeing' at the London School of Hygiene and Tropical Medicine, Keppel Street, W.C., on Wednesday, July 14 at 2 p.m. Admission is free and all interested are invited to attend.

## Association of Clinical Pathologists

The 40th scientific meeting of the Association of Clinical Pathologists will be held in the general lecture theatre of the University of Sheffield on Friday and Saturday, July 16 and 17. The programme is as follows: July 16, 9.30 a.m., Dr Joan Taylor (London), 'The Pathogenicity of the Paracolon Bacillus', 9.55 a.m., Dr R. Goiffon (Paris), 'Diarrhées et des Fausses Diarrhées', 10.15 a.m., Dr J. Ungar (Greenford), 'Distribution of Penicillin in Blood and Inflammatory Tissue', 10.35 a.m., Dr L. C. D. Hermite (Sheffield), 'A Short Review of the Pathology, Diagnosis, and Treatment of Amoebiasis', 11.30 a.m., Dr W. Weiner (Birmingham), 'The Significance of the Coombs Test', 12 noon, Dr Rosemary Biggs (Oxford), 'Dicoumarin and the Prothrombin Time', 12.30 p.m., Dr J. F. Goodwin (Sheffield), 'Clinical Aspects of Anticoagulant Therapy', 2 p.m., demonstrations in the Department of Zoology, 4.30 p.m., Sir Theobald Mathew, 'The Collection and Presentation of Evidence', 5.15 p.m., Dr G. Forbes (Sheffield), 'The Assessment of the Effects of Alcohol', July 17, 9.30 a.m., Dr A. Dick (Sheffield), 'A Simple Method for the Determination of Renal Plasma Flow and Glomerular Filtration Rate using Para-amino hippuric Acid and Sodium Thiosulphate', 9.55 a.m., Dr S. Sevit (Birmingham), 'The Neutral Red Excretion Test of Gastric Function', 10.20 a.m., Dr A. Durupt (Paris), 'Diagnostic de l'Hypothyroïdisme et Surveillance du Traitement par le Test Métabolique de l'Effort', 11.15 a.m., Dr A. H. T. Robb-Smith (Oxford), 'Lipo-melanin Reticulosis', 11.35 a.m., Dr F. O. MacCallum (London), 'The Problem of Serum Hepatitis', 12.5 p.m., Dr J. Murray (London), 'Rapid Slide Method of Rh Grouping', 12.25 p.m., Dr K. B. Rogers (Birmingham), 'Relationship of Specific Gravity of Erythrocytes to Hypochromasia and its suggested effect on the Sedimentation Rate'. The honorary secretary of the association is Dr W. H. McMenemy, Royal Infirmary, Worcester.

## Conference on Civil Engineering Problems

A conference on Civil Engineering Problems will be held at the Institution of Civil Engineers, Great George Street, Westminster, London, S.W., from July 19 to 23, when a number of papers on subjects of importance in Colonial development will be read and discussed. The Rt. Hon. A. Creech Jones, M.P., Secretary of State for the Colonies, has consented to open the conference on Tuesday, July 20 at 10.15 a.m. The conference is open to members of the institution, to engineers and to other officers specially interested, who are employed in the Colonial Service, and to other engineers who are otherwise engaged in civil engineering work in the Colonies. Included in the programme is a lecture to be given by Prof. George MacDonald, M.D., on 'Tropical Hygiene as it Affects the Colonial Engineer', on July 23, at 3 p.m. Details of the papers, lecture, and visits, and application forms, can be obtained from the secretary of the institution at the above address.

## SOCIETIES AND LECTURES

## Monday

MEDICAL SOCIETY OF LONDON 11, Chandos Street, Cavendish Square W.—July 12, 8.30 p.m. *Natural Defences and Disorders of the Respiratory Tract*. Discussion to be introduced by Dr A. W. Proetz and Prof. R. J. V. Pulvercraft.

## Tuesday

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East S.W.—July 13, 5 p.m. The Bertram Louis Abrahams Lecture *Curare and Curarimimetic Drugs* by Dr J. W. Trevan, F.R.S.

## Friday

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields London, W.C.—July 16, 5 p.m. *Growth and Development from the Clinical Aspect of Orthodontics*. Charles Tomes Lecture by Prof. A. F. Jackson (Professor of Orthodontics, Temple University, Philadelphia).

## Saturday

NUTRITION SOCIETY—At Royal Society of Medicine 1, Wimpole Street London, W., July 17, 10.30 a.m. *The Nutrition of Athletes*. Whole-day conference.

## APPOINTMENTS

Duncan Ballantine, M.B., Ch.B., F.R.C.S. Ed., M.R.C.O.G., has been appointed Gynaecologist to Rotherham (Yorkshire) Hospital and Consultant Obstetrician to the Municipal General Hospital Rotherham.

Dr J. K. Craig, of Donnybrook, Dublin, has been granted a Colonial Service Medical Officership in Kenya.

Dr James A. Harbison, Dublin County Medical Officer of Health since 1931, has been appointed City Medical Officer.

Robert John Harrison, L.R.C.P., M.R.C.S., has been appointed Senior Physician at Fulham Hospital.

Isaac Hunter MacIver, M.B., Ch.B., has been appointed a member of the Scottish Health Services Council.

BIRMINGHAM CHILDREN'S HOSPITAL—Assistant Aural Surgeon and Laryngologist Norman L. Crabtree F.R.C.S. D.L.O. Assistant Radiologist Roy Atwell M.B. Ch.B., D.M.R.

DOUGLAS D. M. M.B. B.S. MRCP Assistant Physician Royal Edinburgh Hospital for Sick Children, Sciennes Road, Edinburgh.

DRANSFIELD C. MURRAY F.R.C.S. Orthopaedic Surgeon Ashton under Lyne District Infirmary and Kershaw Children's Hospital.

FINLAY H. V. L. M.B. Ch.B. MRCP DCH Paediatrician Hillingdon County Hospital, Middlesex County Council.

GENERAL HOSPITAL NORTHAMPTON Assistant Consultant Surgeons Derek G. Lambley B.Sc. M.B. F.R.C.S. and E. E. T. Taylor B.A. B.M. F.R.C.S.

HANSTEAD GENERAL AND NORTH WEST LONDON HOSPITAL Haverstock Hill N.W.—Honorary Surgeon to Outpatients A. E. Williams F.R.C.S. Honorary Physician in charge of Physiotherapy Department A. J. Martin M.R.C.S. L.R.C.P. D.P.M.

KIDDERMINSTER AND DISTRICT GENERAL HOSPITAL—House physician Beryl G. Casell M.B. Ch.B. Casualty Officer J. Hubert Beswick M.B. Ch.B.

NICHOLSON W. F. M.B.E. M.D. M.Ch. F.R.C.S., Honorary Assistant Surgeon Manchester Royal Infirmary.

PARKMAN T. H. M.B. B.S. D.P.H. Deputy Medical Officer of Health Hastings.

TOLLAND JOHN L.R.C.P. and S. Ed. D.P.H. Joint Medical Officer for Retford Borough, Retford Rural District and Assistant County Medical Officer Notts County Council.

ZOBB MAX M.D. MRCP First Assistant to Cardiological Department Royal Free Hospital, Gray's Inn Road, London W.C.

## BIRTHS, MARRIAGES, AND DEATHS

## BIRTHS

McCrae—On June 26, 1948, at Ayrshire Central Hospital to Eileen, wife of Dr John S. McCrae, M.B.E. of Runcmead, Catrine, Ayrshire, a daughter.

## MARRIAGES

Kinnish—Chamberlain—On June 22, 1948, at the Church of St. Mary the Virgin, West Derby Village, Liverpool, Raymond Yondy Kinnish, M.B. Ch.B. to Vena Chamberlain.

## DEATHS

Barlee—On June 25, 1948, at Guildford, Surrey, Hobart John William Parlee, M.D., formerly of Tunbridge Wells, aged 80.

Beveridge—On June 25, 1948, at Edinburgh Royal Infirmary, Gordon Beveridge, M.C. L.R.C.P. and S. Ed.

Connop—On June 30, 1948, at Rossland Hatch, Beruchamp, Taunton, Herbert Connop, L.R.C.P. and S. Ed. L.R.F.P.S. Glas. Major R.A.M.C. T.A. retired.

Cooke—On June 28, 1948, Martin Alfred Cooke, O.B.E. T.D. M.R.C.S. L.R.C.P.

Fleming—On June 27, 1948, at 25 Belgrave Crescent, Edinburgh, Colonel Archibald Nicol Fleming, D.S.O. 1 M.S. retired, aged 79.

Forrest—On June 22, 1948, suddenly, Alexander Robb Forrest, M.B. Ch.B. D.P.H.

Hall—On June 26, 1948, at 45 Belgrave Road, Birmingham, John Arthur Hall, M.R.C.S. L.R.C.P., aged 78.

Heggs—On July 1, 1948, at a Jersey nursing home, Thomas Barrett Heggs, M.D. D.P.H. of Dagmar Market Hill, St. Aubins, Jersey, aged 68.

Mossop—On June 25, 1948, at Brierwood, Hythe, Charles Henry Mossop, M.R.C.S. L.R.C.P.

Ross—On June 28, 1948, Thomas Lawrence Ross, M.B. B.Ch. B.A.O.

Tierney—On July 3, 1948, at 46 Gloucester Place, London W., Thomas Tierney, M.D., aged 79.

Tindal—On June 22, 1948, at Stracathro Hospital, suddenly, David Duncan Tindal, M.D. Ed. M.B. C.M.

## Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

### Syphilitic Aortitis

**Q**—What is the best method of treating syphilitic aortitis and how does treatment alter the prognosis?

**A**—Most people nowadays would employ penicillin in the treatment of uncomplicated syphilitic aortitis but would start with very small doses in order to avoid the risk of a Herxheimer reaction. It is advisable to begin with a dose of 500 units increasing fairly rapidly till each injection contains 50 000 units provided there is no untoward reaction. The total dose should be 8 to 10 mega units and injections should be given every three hours. As yet there is little evidence available on the efficacy of penicillin alone, so that iodides, bismuth and arsenic should all be employed as well. Arsenic in the form of neoarsphenamine should be used in doses of 0.1 g. at first, increasing slowly to a maximum of 0.6 g. Treatment should extend over a period of at least two years and most reliance should be placed on bismuth during the second year. Treatment improves the prognosis considerably. Moore (*Modern Treatment of Syphilis* 1943) states that 63 of 75 patients (84%) obtained symptomatic relief, and that in a series of 115 patients adequate treatment reduced the mortality from 42 to 14% over a period of eight years and the incidence of complications, such as aneurysm or aortic regurgitation from 31 to 19%.

### Fluorescent Lighting

**Q**—Is fluorescent lighting injurious to health and to eyesight?

**A**—The efficacy of this type of lighting is the subject of considerable controversy among ophthalmic surgeons. The firms responsible for the manufacture and installation are naturally biased in its favour and they and their representatives do all they can to popularize it. The writer believes that there are factories where the lighting has been tried but where the ordinary tungsten-filament bulbs have been re-installed. Patients certainly complain about fluorescent lighting. In some cases the trouble is due to bad choice of colour, bad positioning of tubes, stroboscopic effects, lack of special methods to remove glare, lack of shadow, bad atmospheric conditions, and inattention to cleansing of the tubes and their replacement when worn out.

The writer's opinion after having seen numerous cases is that, given a healthy and robust eye, properly corrected for errors of refraction, and good working conditions with regard to air-conditioning, freedom from dust, etc., the light has no bad effect if the exposure is not over very lengthy periods but he has no doubt that tungsten light is kinder to eyes which are slightly subnormal.

### Climate and Asthma

**Q**—A patient aged 58, a chronic sufferer from bronchial asthma, bronchitis and vasomotor rhinitis aggravated by cold and damp weather wishes to know whether a sojourn in South Africa, Rhodesia, California or Switzerland is worth a trial to obtain relief. The title of a textbook which guides one in choice of a suitable climate in the treatment of asthma and other bronchial affections would be welcomed.

**A**—It is likely that this patient would derive most benefit from a climate which is warm and dry without being dusty. South Africa or California would meet these requirements. There are few modern textbooks which deal with climatology, although recommendations of the type required will be found in most standard works on the treatment of the affection in question. The classical book on the general aspects of climatology is *Climatotherapy and Balneotherapy*, by Sir H. Weber and F. P. Weber (Smith Elder and Co., London 1907). M. Piéry's *Traité de Climatologie Biologique et Médicale* (Paris,

Masson et Cie, 1934) is a more recent and comprehensive work while E. Hawkins's *Medical Climatology of England and Wales* (London H. K. Lewis, 1923) has a more local application.

### Para aminobenzoic Acid

**Q**—Can para aminobenzoic acid be obtained in tablet form? Are there any dangers from doses of the order of 200 to 300 mg. daily and is the therapeutic activity of this substance proved?

**A**—Para-aminobenzoic acid can be obtained in bulk from several leading chemical manufacturers, but it is not obtainable in tablet form. A dose of 200 to 300 mg. daily is probably quite safe to administer, but leucopenia, nausea, and tympanites have been reported in patients receiving 12 g. or more daily. It has been used in the treatment of certain rickettsial diseases such as Rocky Mountain spotted fever, typhus, and scrub typhus. The dose is from 12 to 30 g. daily. The premature claims for the treatment of grey hair with para-aminobenzoic acid have not been substantiated.

### Control of Micturition after Prostatectomy

**Q**—How long does it usually take to acquire normal control of micturition after the suprapubic removal of an enlarged non-malignant prostate? One patient aged 70 had this operation some months ago and is still unable to micturate especially in the latter half of the day.

**A**—No useful estimate can be given of the time taken to acquire control of micturition after a suprapubic prostatectomy, as it varies so much in different patients. An elderly man is likely to take longer than a younger one. It would be useful to pass a catheter and to discover whether there is any residual urine. The patient should also exercise his sphincter by stopping the stream during micturition and restarting it. Voluntary stimulation of the sphincter can also be supplemented by electrotherapy in the form of stimulation of the perineal muscles with a faradic or sinusoidal current.

### Loss of Weight after Hysterectomy

**Q**—Does loss of weight usually follow hysterectomy? A patient aged 36 has lost 3 st (19 kg) in the past three years following hysterectomy and removal of one ovary. The wasting is confined to the trunk and upper limbs, the lower limbs being quite muscular. The face is wrinkled and drawn. Her appetite is good, she feels well and she leads an active life. Is Simmonds's disease a possibility?

**A**—Neither removal of the uterus nor removal of the ovaries usually causes a significant loss in weight. Bilateral oophorectomy is sometimes followed by an increase in weight although this is often only temporary. It seems unlikely that the wasting in this case has any direct relation to the operation and another cause should be looked for. There is nothing in the account to suggest Simmonds's disease, which is not as was formerly supposed characterized by cachexia.

### Treatment of Coccydynia

**Q**—A thin delicate woman aged 55 complains of pain in the terminal coccygeal vertebra. This pain has been present for a year and is aggravated on sitting or lying. Examination reveals a prominent terminal vertebra with a bulbous contour. Would injecting the area with one of the sclerosing fluids used for varicose veins be effective? What other treatment would you recommend?

**A**—The condition described appears to be a form of coccygodynia, a complaint that unfortunately it is not always easy to cure. In view of the bulbous contour of the coccyx it would be helpful to have a radiograph taken to see whether there is any cyst formation or other bone disease. If there is, or if any other organic lesion—e.g., displacement—is present, there might be an indication for excision of the coccyx. In the ordinary case of this kind, however, x-ray changes are not present and surgical treatment is not usually required. Treatment by local injections into the area of tenderness is sometimes helpful. Solutions commonly used are procaine (2%) or "procaine." Sclerosing fluids are not advised for injection in this site. If injection treatment fails, physiotherapy, preferably

in the form of short-wave diathermy will often afford considerable relief. If there is no organic lesion 'time' is the best healer.

### Inoculation and Vaccination

**Q**—*A party of some 30 senior schoolboys propose to visit France in August. Would you please advise me on the necessity for prophylactic treatment against the enteric group and small-pox? Most of these boys are adolescents and it is unlikely that they have been vaccinated previously.*

**A**—Inoculation against the enteric group should be recommended to any person proposing to travel on the Continent, since the hazard of typhoid fever in this post-war period is not negligible. Boys of 14–18 years should be given the adult dose of TAB vaccine—two injections at 10–14 days' interval given in the late afternoon or evening with an aspirin tablet prescribed at bedtime and no strenuous exercise next day.

Primary vaccination of adolescents against smallpox, besides causing a fair degree of local and constitutional upset, does carry a very small risk of postvaccinal encephalitis. Where, therefore, there is no compulsory regulation requiring a certificate of vaccination within the past three years, it is better not to vaccinate unless there is any evidence of smallpox being prevalent in the country to which the boys are travelling. Occasional cases and outbreaks are, of course, liable to occur in France by introduction from North Africa or the East, but the risk for a group of boys going on a conducted tour must ordinarily be very small.

### Treatment of Thrombophlebitis

**Q**—*Would dicoumarol be beneficial in the case of an active woman of 39 who has suffered from thrombophlebitis of both legs for six months? The condition improved in hospital and afterwards at home when she was kept in bed, but in each case when she was allowed to get up the pain and swelling returned with marked tenderness in the thighs.*

**A**—This type of case often benefits from dicoumarol combined with supportive bandaging with 'elastoplast' or elastic bandages. The former should be worn all the time and the latter in the daytime only. Sleeping with the head low is also of value. The dicoumarol should be administered with care and with a view to keeping the prothrombin time double the normal, in some of these cases a two-months' course is necessary. Some patients (and doctors) are inclined to regard the swelling and aching which persist after subsidence of the attack as a continuation of the condition. Support is sufficient for this, dicoumarol is necessary only when tenderness and induration persist. Focal sepsis must be excluded, and if the blood pressure is low it may be as well to prescribe ephedrine or amphetamine.

### Vitamin B and Hair

**Q**—*What preparation of vitamin B (whole complex) would you advise for poor-quality hair following pregnancy? Can better results be obtained with parts of the B complex? Are any ill effects likely with large doses of individual B factors?*

**A**—There is no preparation of the vitamin B complex that improves the poor quality of hair. Hair lacking in lustre ('staring' hair) has been described in undernourished subjects, particularly in Newfoundland, but it has not been possible to ascribe it to lack of any specific vitamin. Para-aminobenzoic acid has been used for the treatment of grey hair, but controlled observations have failed to substantiate the early claims for it. The uncontrolled use of this drug is inadvisable, as it may cause leucopenia.

### The Safe Period

**Q**—*A patient has consulted me for the exact details of the so-called safe period. She is 34 and has one child aged 3½ years. I have replied that there is no absolute safe period during the menstrual cycle but I would welcome an expert's opinion—what is the modern view on this form of contraception?*

**A**—The existence of a 'safe period' is based on the fact that ovulation usually takes place  $14 \pm 2$  days before the onset of the next period and that the ovum and spermatozoa retain

their fertility for not longer than 24 and 48 hours respectively. The time of ovulation, however, is not so constant as to make the safe period absolutely safe, but it is relatively so. Indeed, in some women it is remarkably reliable. In the case in question the cycle usually lasts 27 or 28 days with an occasional shortening to 25 or 26 days. The fertile period is therefore between the 7th and 18th days, counting from the first day of the last menstrual period, any other time in the cycle should be reasonably safe. See also replies to questions previously published in the *Journal* (1943, 2, 286, 1944, 2, 260).

### Spina Bifida and Incontinence

**Q**—*How often is spina bifida responsible for incontinence of urine? I have in mind a boy of 7 years who suffers from incontinence dribbling of urine occurring equally during the day and at night-time. It started about three years ago and is getting worse. After a thorough investigation in hospital the condition was considered to be due to occult spina bifida. An operation is suggested presumably to relieve hypothetical traction on the cauda equina. What results have hitherto been obtained by such an operative procedure and what risk is inherent in the operation?*

**A**—Spina bifida often causes incontinence of urine. The results of operation are uncertain. Sometimes traction can be relieved or adhesions between nerve roots and the arachnoid can be divided, with relief of urinary incontinence. But more often the result of operation is disappointing. In the case mentioned a boy aged 7 began to have incontinence only three years ago. This is a rather unusual story for spina bifida, and while the diagnosis may be correct there might be some other cause for the incontinence.

## NOTES AND COMMENTS

**Mauling by Tigers**—Dr C S P HAMILTON (Kapnapahar, E. Bengal) writes: It has fallen to my lot to treat many animal maul cases. In this district tiger and panther maul casualty patients are the most frequent. The commonest wounds are claw wounds, which can be truly incised as well as lacerated. Out of the last four cases coming under treatment this year, they have all been claw wounds. This is due to the animal—often female with young—being suddenly frightened, in consequence it rushes out and hits wildly with its fore paws, and generally runs off. One of the worst cases I had suffered from an apparently incised wound from the left mastoid down the anterior triangle of the neck exposing the carotid; in addition there were lacerated wounds on the right cheek. If the animal wishes to kill it seems to first strike with the paws, then pounce on the victim, in my experience nearly always attacking the head and neck. Scalping is quite common in tiger wounds. One such case showed teeth wounds—lacerated—over both mastoids and a horizontal lacerated wound in the occipital area, with claw wounds over the left scapula. The woman was kneeling on the ground doing up a bundle of wood when the man-eater attacked her from behind.

Treatment now is simple. Clean the wounds, remove torn tissue, fill with sulphonamide powder, and dress with petroleum jelly, penicillin, and sulphonamide paste. Inject penicillin, and the wounds heal by almost first intention. If these victims are not killed on the spot, they nearly always survive. Our last seven cases have a 100% recovery.

**Care of Teeth in Children**—Mr J H BADCOCK (Bury St Edmunds, Suffolk) writes: Referring to the reply in "Any Questions?" (June 12, p. 1165) on the care of the teeth of children, surely the all important reason for saving the temporary teeth is the preservation of their masticatory function at its maximum until their permanent successors take their places—years when growth is most active and perfect nutrition most essential.

# SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY JULY 10 1948

## British Medical Association

### ANNUAL REPRESENTATIVE MEETING, CAMBRIDGE, 1948

TUESDAY JUNE 29

The concluding session of the Annual Representative Meeting opened on Tuesday, June 29 at 9.45 a.m., with Dr J. B. Miller in the chair.

#### An Omnibus Vote of Thanks

The first business was to accord, on the motion of the Chairman, a vote of thanks to all who had contributed to the comfort, pleasure, and convenience of the Representative Body. These included the Lord Lieutenant of Cambridgeshire, the Vice-Chancellor and Members of the Senate, the Mayor and Mayoress, the Town Council and municipal officials and a number of other local persons, also the Honorary Local General Secretary Dr Salisbury Woods, the Honorary Local Science Secretaries, Dr M. M. Wilson and Mr R. M. Fry and the members of the local Executive Committees.

The vote of thanks was accorded by acclamation.

#### Miscellaneous Motions

In the absence of the representative of Westminster and Holborn a motion was formally proposed from the Chair that steps be taken by the Council to set up a Standing Legal Committee.

The Chairman of Council said that he did not appreciate the reasons for this proposal, which was put forward without any suggested reference or functions for such a committee to perform. He hoped that it would not be accepted.

The motion was lost.

Dr Elsie Warren (Kensington and Hammersmith) moved that through the *Journal* or in other ways it should be suggested to members of the Association that they might volunteer to do part of the daily work of representatives during the B.M.A. Executive and other meetings.

This was agreed to.

Mr Weldon Watts (Newcastle-upon-Tyne) moved: 'That every session done by a practitioner should be paid for at full rate without any limitation of the number of sessions taken.' He objected to the principle of limitation of the number of sessions for which the practitioner was paid. This was carrying on the tradition of the Emergency Medical Service. Two groups were specially hit by this limitation—namely, young men back from the Services who had not had time to establish a reasonable private practice and the 'super-specialists' who did all their work in hospital. He hoped that this motion would go to the Negotiating Committee for consideration and action.

Mr Simson Hall (Edinburgh) supported the proposal. Domiciliary consultations were an extremely important point to some specialists. This was probably one of the most fruitful ways in which the energetic and keen surgeon might obtain extra remuneration, and he thought they should adopt the attitude that such a man should be enabled to make what his reputation and ability entitled him to make and not be limited by any financial ceiling of this kind.

Dr Craig (Newcastle) supported the proposal which was carried.

#### Payments of Expenses of Representatives

Dr S. Noy Scott (Plymouth) moved that in order that suitable representatives should not be prevented from attending meetings on the score of cost, reasonable out-of-pocket expenses in addition to first-class railway allowance be paid by the Association, even if the expenditure should necessitate an increase in the annual membership subscription.

He said this was a hard annual. It was high time that representatives should be paid reasonable out-of-pocket expenses. This was the more important in view of the continual cry for younger men in the Association.

Dr H. G. Dowler (Gloucestershire) moved an amendment which made the motion include members of Standing Committees, and for reasonable out-of-pocket expenses substituted expenses reasonably incurred in employing locum-tenents. As the Plymouth motion stood he could not agree to it. It was an honour to be chosen to come to the Representative Meeting.

Dr J. O. McDonagh (Perth) asked what Plymouth meant by 'reasonable.' He hoped they meant 'reasonable towards the B.M.A.' A sum of £2,000 was already spent on Council and committee meetings and this new proposal would mean a very heavy extra expenditure. This would necessitate the raising of the subscription which was questionable policy at the present time. Were representatives deterred from coming to the meeting because of expense? He greatly doubted it. They felt rewarded by the experience and contacts they made there. Nowadays most of the world was wanting something for nothing. There were very few people who were willing to do something for nothing. They as representatives were asked to continue to do that, and he hoped they would be allowed to do it.

Dr G. J. Meikle (Worcester and Bromsgrove) speaking as a recently elected representative said that he felt it an honour to come and while he sympathized with the suggestion behind the Plymouth motion he thought they should continue to act as voluntary representatives rather than seek to form a class of part-time professional medical politicians.

Dr D. H. Muir (Fife) said that he gained a great deal in contact and experience by coming to the Representative Meeting and he wanted both the motion and the amendment turned down.

Dr A. C. E. Breach (Bromley) said that to the best of his knowledge this would be his last Representative Meeting and therefore this motion would not affect him. He hoped, however, that it would be realized that there was a good deal of sense behind it. Those present were there presumably because they could afford the expense but others were absent because they could not afford the expenditure nor the serious loss of earning power. There was a danger in the present system that representation was being confined to men who were financially established and this tended to exclude those to whom expense was a matter of prime consequence.

Dr Elsie Warren (Kensington and Hammersmith) said that it was true that not many young men attended, but were they really wanted?

Dr F Gray (Wandsworth) reminded the meeting that last year the principle of payment was affirmed but not by a sufficient majority. It was becoming apparent that it was more and more difficult to get men to carry out the Association's work because of the extra strain imposed on them by the National Health Service, under which they would carry a greater burden than ever before. The expense to members was unequal, and so far as the London members were concerned it was trivial as compared with their provincial colleagues. He hoped the matter would be referred to Council so that it could be dealt with again.

Dr F E Gould (Birmingham) said that he felt that this question of payment of expenses might alter the whole work of representatives of the Association. There was another hard-working body of men whose expenses should be paid—the Divisional Secretaries. If they started paying expenses, where would it stop? He hoped the motion and amendment would be rejected.

Dr W D Steel (Worcester and Bromsgrove) agreed that the burden of committee work was heavy, but he would strongly oppose any interference with the voluntary nature of the work. Committee work had been increased very greatly under the National Health Service Act and it seemed wrong that the machinery of government should be carried out voluntarily by members of the medical profession. If any payment was to be made it should be to members of statutory committees taking part in the administration of the new Health Service. He hoped that the motion and amendment would be turned down promptly.

Dr N J Cochran (Burton-on-Trent) said that payment for people doing Government work was already made, but work for the Association should be done voluntarily, gladly, and willingly.

Dr Brown (North Staffs) said that this was the first time he had been a representative, he was honoured to represent his constituency. He opposed the motion.

Dr O C Carter (Bournemouth) pointed out one anomaly of the present situation, that if a member had to attend standing committees on two consecutive days he might have time to get home at night, thus saving himself the expense of a hotel, but it cost the Association two railway fares.

Dr J A Pridham (Dorset) hoped that the meeting would turn down the amendment and vote on the main motion. He would ask the members to remember the voluntary levy—that wherever a Division felt that a member was put to considerable expense it could put up a voluntary fund to assist him and do his work while he was away. That suggestion had worked in some areas, his own colleagues had been very generous to him. He hoped the vote would be taken on the principle and not merely on a reference back to Council, and that the decision would be made by the necessary two thirds majority.

Dr S Noy Scott (Plymouth) also hoped that the amendment would be rejected and a vote taken on the straight motion.

Dr H G Dowler (Gloucester), in reply, said that the voluntary principle should remain, but why were railway fares paid? In order to equalize the position between those who came from long distances and those who were close to the place of meeting he would ask those in partnership practices to remember their single-handed brethren who had to pay a locum tenent as well as their expenses.

The amendment to insert "members of standing committees" and to pay expenses "necessarily incurred in employing a locum tenent" was lost.

Dr J W Bone, speaking to the Plymouth motion, said that there were many reasons for doing what was desired, but it wanted a good deal of consideration because of the repercussions which would arise. The last Special Representative Meeting cost the Association £1 250 in railway fares and there had been several Special Representative Meetings in the last year. The normal subscription was £3 3s, but the average subscription was about £2 5s, because reduced subscriptions were given to the newly qualified and to Service personnel, and there was a free list, and if it was decided by the necessary majority to pay these expenses there would have to be an increase in the subscription. The slogan should be "No practising medical man can afford to stay outside the Association," and the subscription should be kept low enough to enable this to be accom-

plished. This aspect of the question should be considered very carefully, and if there were any doubts about it the motion should not be carried.

Dr T W Morgan (Kingston-on-Thames) proposed a further amendment, "That the payment of expenses in individual cases should be a matter of recommendation by the Divisional Executive Committee to headquarters" (No). In certain areas it was well known to the secretaries of Divisions that there were people who were willing to go to meetings in London and elsewhere but who honestly could not afford it. There were these few cases, and it might be that recompense should be given.

Dr A C E Breach (Bromley) asked how one representative could be paid and another not. On the other hand, if they were all given payment it would of course, be open to anyone to hand it back to the Association.

Dr J A Pridham appealed to the meeting to turn down the amendment. If a Division or Branch encountered a difficulty surely it would be possible for it to make suitable arrangements.

The amendment by Kingston-on-Thames was lost.

In replying to the motion Dr Noy Scott made the confession that in his Divisional meeting both he and his fellow representative consistently voted against this proposal, but as representing his Division he had to bring it forward.

The motion to allow reasonable out-of-pocket expenses to representatives was lost by a very large majority.

### Method of Election of Council

Dr C F Mayne (Plymouth) asked the Council to report progress on that part of the Plymouth resolution adopted at the Annual Representative Meeting 1943, that consideration be given at an early moment to the election of Council on a more direct and better geographical basis. Members at the periphery, at any rate in his area, were anxious to know what was being done in this respect. He instanced the circumstances of his Group Area. It extended from Land's End to Gloucester and Worcester, and it was quite unfair to ask their representatives to come down as often as they would like to have them in order to meet distant Divisions. He did not bring forward this motion in criticism of the representatives of his Group but it was felt that it would be better if direct representation were to a certain extent modified.

Dr Pridham said that this matter was brought forward in 1943 and the Council, after consideration, was not in favour of taking action. It recognized that there were certain anomalies in the grouping of Branches, but it was satisfied that the removal of such anomalies would only give rise to similar difficulties in respect to other areas. The Organization Committee had given constant attention to the whole structure and machinery of the BMA and was not of opinion that it was wise to make more drastic changes at the moment. They wanted to see the effect under the new Act.

It was agreed to proceed to the next business.

### SCIENCE

Dr R G Gordon (chairman of the Science Committee) moved approval of the Annual Report under "Science."

He said that the Science Committee was doing important work—work which would become more important in the future. The most striking event of the year had been the removal of the library into its new premises, and here he wished to thank the Librarian, Mr Shields, and his staff for the work they had done in transferring the library without any serious inconvenience to members. The Council had been asked for additional money to spend on the purchase of medical books, which were now coming out with increasing frequency and unless bought immediately were soon out of print. The library, although it received many journals through the Abstracting Service, also found it necessary to purchase a number.

He mentioned the prizes given by the Association and expressed thanks to the adjudicators. He referred in particular to the new venture whereby prizes were offered for essays by nurses. The response had been gratifying, and although the level of merit was varied, in each section there were essays of a very high order indeed and well deserving of praise.

Another new institution was the Insole Scholarship for research into the causes and cure of venereal disease. The Divisions were asking for BMA lectures increasingly.

The Report was approved.

### MEDICAL FILMS

Mr Dickson Wright, chairman of the Film Committee moved approval of the report under "Medical Films". He said there had been a proposal that the Film Committee should become a Standing Committee of the Association, but it was thought better that for the time being it should continue as an *ad hoc* committee. Accommodation had been put aside for the work of the Committee at headquarters, and it was the intention to set up a film library. An effort had been made to obtain films of special interest for general practitioners and it was hoped to get this whole matter of films on a proper footing so that it would be a credit and a great amenity to the Association.

Dr R P Liston (Tunbridge Wells), speaking as deputy chairman of the Committee, said that the scope of films in medical education was very wide and the B M A was embarking on a most important project. A medical film library was being set up at Headquarters, and it was hoped that it would in course of time be second to none in the world. It would cost a lot of money and take up a lot of time, and he appealed to members who were interested in films and who had actually made medical films to lend them so that copies could be made for inclusion in the library. If such members felt disposed to give their films the Committee would be more than delighted.

Mr Dickson Wright endorsed what Dr Liston had said, and the report was approved.

### PUBLIC RELATIONS

Dr H Guy Dain, as chairman of the Public Relations Committee, moved approval of that part of the report. He said that this had been the most active year since the inception of the new department and there was every reason for congratulation on what had been accomplished. On the question of the National Health Service and the Association's negotiations the Press had been helped on all sides by the Public Relations Department and its officer, and the benefit had been felt in the understanding of the Association's ideas and policy thus achieved. An information service on medical matters of all kinds—not merely political matters—was being built up so that the constantly increasing number of inquiries which the Press were making could be answered quickly and efficiently. The effect of this was difficult to measure, but the support received during the past months had been most helpful. A really effective Public Relations Department had now been established.

Dr A C E Breach (Bromley), in offering congratulations to the Department on its extraordinarily fine work, asked whether the Chairman of Council could amplify the report a little. Some members were perplexed by the failure of the Department to send out to members the posters, handbills, and handbooks promised as a matter of urgency at the Special Representative Meeting in March.

Dr Scott (Barnet) hoped that Headquarters "in the flush of enthusiasm for the new Service" would not forget those members who were desirous of staying out of the Service or those who, while entering the Service, wished to retain an interest in private practice. Recent letters in *The Times* had been confusing in their effect. An article in a London evening paper last week stated that people requiring dental benefit could get it provided they could find a dentist who would undertake it on presentation of a medical card. Dental benefit was equally applicable to those who had registered and those who had not. It was also stated that ophthalmic benefit was on the same basis. Such statements could do a great deal of harm, and he hoped that the Public Relations Department would do its best to refute them.

Dr F E Gould (Birmingham) paid a tribute to the work and courtesy of the Public Relations Officer, Mr Pringle. With regard to the material sent to Divisional Secretaries for distribution to their members he wondered whether the Public Relations Committee could consider some method of sending them out to individual practitioners in order to help secretaries.

Dr G J Meikle (Worcester and Bromsgrove) asked if representations could be made to the Ministry of National Insurance to ensure that local offices did not give wrong information to people making inquiries about the National Health Service. Wrong information was given to one of his patients, and when

he protested to the manager he was informed that they were not supposed to give information on the Health Service whereupon he suggested that if the staff did not know the answers they should not give misleading information. This was probably going on all over the country.

Dr A G Heron (Bristol) said he was also worried about the contradictory statements made from time to time. His Division would like to know whether anything was done about the recommendation passed at the last Special Representative Meeting that steps be taken to inform the public that at its inception not all the promises made in the National Health Service could be fulfilled. Very little of this recommendation seemed to have been carried out.

The Chairman of Council, in reply, said that following the plebiscite in February literature of all kinds was put in hand, but it was difficult to get it printed because of the shortage of paper. By the time it was ready the Minister had changed his mind, and it was not issued. So much of it dealt with the danger of a whole-time Service created by regulation. The Minister's statement put the material out of date. Approximately 500 000 leaflets on the private practice question had been issued to doctors and explained to patients what was their position on the subject of private practice. When a newspaper published a statement which was inaccurate it was not very easy to catch up on it, papers were not always willing to correct statements, and it often did more harm than good if they could be persuaded to do so. After July 5 leaflets would be issued to practitioners with regard to the deficiencies in the Service which were bound to occur, and the responsibility was placed where it should properly lie. The medical profession would do their utmost to give good service to the public, and what deficiencies there were were not their fault.

The Association was in considerable difficulties with Ministries other than the Ministry of Health. The Ministry of National Insurance issued instructions which Headquarters did not see, and it took a little longer to catch up on them. A letter had arrived that morning saying that the Ministry of Education was issuing an instruction to schoolmasters to tell them to sign on their pupils on the school doctor's list, which was news to the office. This kind of thing became known only when complaints were received from members. The Committee was very anxious that the public relations service should give every satisfaction, it was very pleased to receive comments, criticism was expected, but constructive and helpful suggestions were received with gratitude. He hoped to get the support of the whole profession in showing that the Association's public relations work was as good as anybody's in the country.

### PSYCHIATRY AND THE LAW

The Annual and Supplementary Reports under this heading were submitted for approval by Dr Doris Odum. She said that the Committee consisted of magistrates and doctors in equal proportions and there were also observers on it from the Home Office, the Ministry of Education, and the Board of Control. It came into being in the early part of 1946 on the initiative of magistrates who found that they had many problems in relation to unstable adults and children which caused them a great amount of anxiety and distress because they did not know how to deal with them. More and more problems were cropping up to be dealt with, and reports had been published the first of which was concerned with the adolescent girl. The work had lain in three fields: the Committee had first to prepare recommendations for emendation of the Criminal Justice Bill, now before Parliament, then the memorandum in Appendix VI of the Supplementary Report on enuresis, particularly in relation to delinquency, was prepared. Magistrates said that they had quite a number of children in the juvenile courts who suffered from enuresis, it was obviously a contributing factor in their delinquency, and the Committee tried to deal with it and make suggestions for the solution of the problem. At present the Committee was engaged in the preparation of a memorandum on sexual offences a problem of great social importance. Although it would not be published until the discussion on the Criminal Justice Bill had been finished it was hoped that it would be of great help to the legal profession.

Dr J G Thwaites (Brighton), commended the work of the Committee. He said that its reports were eagerly looked for by lay people who undertook social work throughout the country, and this quiet steady work brought much credit to the Association.

The Report was approved.

The Annual Report under 'Armed Forces, in the absence of the Chairman of the Armed Forces Committee, was formally moved and approved.

### SCOTLAND AND WALES

Dr G MacFeat, Chairman of the Scottish Committee, outlined the various matters relating to Scotland which were given in detail in the Annual and Supplementary Reports of Council. He referred to the new machinery for the organization of the Association in Scotland and forecast the usefulness of the Regional Consultants and Specialists (including Hospitals) Committees, and of the Central Committee. He referred also to the Report of the Working Party on the recruitment and training of nurses in Scotland, the Scottish public relations machinery and the discussions which had taken place with the Department of Health on the various sections of the National Health Service (Scotland) Act.

The Report was approved.

Dr H R Frederick, Chairman of the Welsh Committee, introduced the section under "Wales". The Welsh Committee had been active during the year and they had been interested in the fact that Wales and Monmouth had been included as a region under the new Act.

This Report was also adopted.

### MEDICAL BENEVOLENCE

Dr Janet Aitken, Chairman of the Charities Committee, moved the Report under Medical Benefit. The Association had £11 500 to distribute among charities during the year—a large increase on the amount for 1945-6. But she did not want anyone to think that the charities in which they were interested did not need more support. The Royal Medical Benevolent Fund had committed itself to a new undertaking on behalf of the aged, and the expenses of Epsom College were going up by leaps and bounds. She also referred to the action of Swiss doctors in giving holidays to the children of British medical men who were killed in the war. A magnificent holiday of three months was given to 92 children who went in three parties.

Dr F M Rose (Preston) asked for special consideration for the claims of Epsom College, and Dr D F Hutchinson (West Middlesex) made an appeal for greater support for medical charities in general.

In reply to questions, Dr Macrae (Deputy Secretary) said that the work under the Medical War Relief Fund was still going forward. The Distribution Subcommittee met regularly once a month. Applications were still being received from people who came within the scope of the Fund, but by the time the balance was expended it was hoped that they would have completed the purpose for which the Fund was formed. He added that when the Committee decided to give a fairly large sum to a widow to help her with the education of her children over 5 years the money was paid to her yearly. By far the greater part of the money paid out had been in the form of gifts.

### VOTE OF THANKS TO THE CHAIRMAN

This completed the business before the Annual Representative Meeting.

Dr H W Pooler moved a vote of thanks to the Chairman, Dr J B Miller, one of his oldest personal friends in the Association. The distinguishing characteristics of Dr Miller's chairmanship had been his tolerance, forbearance and ready wit. His term of office had coincided with the most momentous period in the whole history of British medicine, and many difficulties had been surmounted as a result of the qualities he had exhibited.

The vote of thanks was accorded with loud cheering, the representatives rising in their places.

Dr J B Miller said that during the three years of his office there had been seven Representative Meetings. Although conducted amid alarms and excursions the meetings themselves were on the whole peaceful and reached decisions in a judicial manner. Despite their fears there had been few or no casualties, and the membership of the Association was still increasing. The success of these meetings had been due to the representatives themselves, who were now experienced in the affairs of the Association, the future of which was safe in their hands.

He then proceeded to invest his successor, Dr E A Gregg with the badge of office. He said that Dr Gregg had presided for eleven years over that virile and exuberant body the Insurance Acts Committee, and that being so he was fit for any chairmanship.

Dr Gregg, who was heartily applauded on taking the chair, said that he had been looking through the list of past Chairmen of the Representative Body and he felt that he was entering upon a wonderful heritage and a great responsibility. He felt like John Bunyan, who spoke of his experiences on reaching heaven. There were three great surprises—that there were people there whom he did not expect to find, that there were not people there whom he did expect to find, and, the greatest surprise of all, that he was there himself. (Laughter.)

The meeting terminated at 12 30 p.m.

### Correction

We regret an obvious error in reporting (*Supplement*, July 3, p. 22) that the eight members of the new Council were elected by Grouped Branches not in Great Britain or Northern Ireland; this should of course, have been 'by the representatives acting together'.

## 116TH ANNUAL GENERAL MEETING

The 116th Annual General Meeting was held in the Large Examination Hall, Cambridge, on Tuesday, June 29, 1948, at the termination of the Annual Representative Meeting. Sir Hugh Lett, Bt., occupied the Chair.

The Secretary read the notice convening the meeting.

The Minutes of the last Annual General Meeting held in London on July 22, 1947, and published in the *Supplement* of Aug. 2, 1947, were confirmed.

### Induction of President

Sir Hugh Lett then inducted Sir Lionel Whitby as President of the Association, 1948-9, and invested him with the Presidential badge of office. He said that looking at Sir Lionel's youthful appearance they might be surprised to know that he fought in the first World War with great distinction and was awarded the MC and took his majority at the age of 22. Unfortunately he was seriously wounded. After the war he entered medicine and devoted himself to bacteriology. He soon became the most distinguished bacteriologist in the country. Some would recall the value of the services he rendered to King George V during his serious illness, from which he recovered. It was to Sir Lionel that they owed the chemotherapeutic treatment of pneumonia, for it was he who discovered the action of sulphapyridine against the pneumococcus. It would be difficult to overestimate the enormous benefit and the number of lives saved as a result of that treatment. Then he devoted himself to the study of blood and became an authority on haematology. When the second World War broke out he was appointed to the charge of the Army's Blood Transfusion Service at Bristol, and again literally thousands of lives were saved as a result of his work. Later he was appointed Regius Professor of Physics in Cambridge University and Master of Downing College.

That day the Association had the great privilege of welcoming him as its new President. His personal qualities had endeared him to those who knew him, and his name would take a very high place among the distinguished names of Presidents.

Sir Lionel Whitby, who then took the Chair, said how very happy he was to be elected as President. Some of them would

remember the last meeting of the Association in Cambridge in 1920, when the President was his famous predecessor as Regius Professor of Physic, Sir Clifford Allbutt. That meeting at Cambridge in 1920 was, like the present one, the first provincial meeting to be held after a World War. Civilization was indeed at the crossroads, and they in the medical profession were likewise caught up in the toils of the social and economic upheaval that had followed upon two wars.

'None of us can say,' Sir Lionel continued, 'how the great State experiment which is to begin next week will work. Most of us have given considerable thought to the implications, effects, and practicability of the scheme. In common with most others I am considerably apprehensive, not so much of inefficiency, not so much of frustration, nor even of undesirable control, because all that can be most vigorously countered by our great Association, and also by the public itself provided it is suitably informed, I am more apprehensive of a more subtle aspect, and that is the loss of the personal and human touch without which the whole soul goes out of the profession of medicine. (Applause)

#### Appointment of Auditors

On the motion of Dr C F Mayne, seconded by Dr F M Rose, it was unanimously agreed.

That Messrs Price, Waterhouse & Co be and they are hereby appointed Auditors of the British Medical Association until the next Annual General Meeting.

#### President-Elect

The President reported that Dr C W Curtis Bain, physician, Harrogate General Hospital, had been elected by the Representative Body as the President of the Association, 1949-50.

Dr Curtis Bain, who was heartily welcomed, briefly thanked the Association for the honour done to him and to Harrogate and said they would do their best to make the Association very welcome next year.

#### Vote of Thanks to Past President

The Chairman of Council (Dr H Guy Dain) moved.

That the hearty thanks of the Annual General Meeting of the Association be given to the retiring President, Sir Hugh Lett, for his services as President, 1946-48.

He said that when Sir Hugh Lett accepted the invitation to become President he brought great gifts to this high office. They were grateful to Cambridge that the University had recognized his services by the honorary degree which he received at the hands of the Chancellor, Field Marshal Smuts only a fortnight ago. If the Association had in a small way helped Sir Hugh Lett to acquire a new distinction they were grateful. When he accepted the invitation to become President he did so in no perfunctory spirit, and he had been most helpful with his advice and interest on the Council and Committees.

The vote of thanks was accorded by acclamation, the members standing and applauding.

Sir Hugh Lett said he was deeply touched by the extremely kind words of the Chairman of Council. He wished that he better deserved them. It had been a great privilege to work with the Association during two years. Some people inside and outside the Association had been inclined to criticize it, calling it a minor trade union but no one could work at B M A House, even for a year, without being enormously impressed by the wide field that the activities of the Association covered. It was not simply a question of seeing that medical men got fair terms for their work. The Association did much on its scientific side, through scholarships and lectures, through its great *Journal* through its Medical Abstracting Service, and its specialist journals, and through its library. He hoped that in the new Empire Medical Advisory Bureau they would have an organization of the greatest possible benefit for their friends from overseas.

On seeing the activity of the Association at close quarters and the able men who sat on its Councils and Committees he felt the utmost confidence that the Association would go on to greater achievements.

The meeting then adjourned until 8.30 p.m. for the President's Address to be given at the Senate House.

### EXTRAORDINARY GENERAL MEETING

An Extraordinary General Meeting of the Association was held in the Large Examination Hall, Cambridge, on Tuesday, June 29, 1948, immediately following the Annual General Meeting. The Chair was taken by the President, Sir Lionel Whitby.

The Secretary read the notice which appeared in the *Supplement* of June 5, 1948, as follows:

Notice is hereby given that an Extraordinary General Meeting of the British Medical Association will be held in the Large Examination Hall, Bene't Street, Cambridge, at 12.30 o'clock in the afternoon, or as soon thereafter as the Annual General Meeting of the Association shall be terminated, when the following resolution, with or without amendment, will be proposed as a Special Resolution.

#### Resolution

That the Articles of Association be altered in the manner following:

(i) By inserting in Article 3 after the words "The Medical Acts the words and figures" "or the Medical Practitioners and Pharmacists Act, 1947".

(ii) By deleting from Article 10 (c) in line 6 the words "for India or".

The President moved.

That this Extraordinary General Meeting amend Articles 3 and 10 (c) of the British Medical Association in the manner above indicated.

The motion was carried unanimously, and the meeting terminated.

### ADJOURNED ANNUAL GENERAL MEETING AND PRESIDENT'S ADDRESS

The adjourned 116th Annual General Meeting of the Association was held in the Senate House, Cambridge, on the evening of June 29. The famous hall was filled with an assembly numbering 1,000, very many of whom were in academic robes and this with the dresses of the ladies made a brilliant spectacle. The President, Sir Lionel Whitby, had on his right the Vice-Chancellor of the University, and on his left the Mayor of Cambridge. On the dais also were principal officers of the Association.

The proceedings began with the introduction to the President by the Chairman of Council of the following delegates from kindred Associations:

Major-Gen E A Moyes (American Medical Association), Dr R C J Meyer (Medical Association of South Africa), Dr P T O'Farrell and Dr A Ryan (Medical Association of Eire), Dr A Batty (Indian Medical Association), Dr Md Ibrahim and Dr Choudury (Pakistan Medical Association), Dr W Demuth and Prof Karl Fellingner (Austrian Medical Association), Dr Moller-Nielsen (Danish Medical Association), Dr B Frankenhäuser (Association of Physicians of Finland), Dr A Codouris (Medical Association of Greece), Prof Joann Saemundsson and Dr Karl Sirand (Icelandic Medical Association), Dr Stig Berseus (Swedish Medical Association), Mr E Rothlin (Swiss Medical Association).

The following representatives from Overseas Branches were next presented:

Dr E J Foley (Tanganyika), Dr F J Wright (Kenya), Mr J H G Robertson (Matabeleland), Dr J N P Davies (Uganda), Dr H J Ham and Dr C G L Stening (New South Wales), Dr E W Duncan (New Zealand), Dr G H McQueen, Mr J L Steele Scott, and Dr J C Lum (South Australia), Dr J Gowland and Dr W Nelson (Victoria), Dr G Fraser (Assam and Northern Bengal), Dr V H L Anthonisz (Ceylon), Dr H P L Ozorio and Dr A W Woo (Hong Kong and China), Dr D W G Farris and Dr R D Gross (Malaya), Dr Masood Ahmed (Punjab), Dr B Gillette (British Guiana), Dr J C R Buchanan (Fiji), Dr C Michie (Gibraltar), and Dr J Cauchi (Malta).

Dr Dain then introduced to the President Dr J W Bone of Luton, the late Treasurer, who on the previous day had been awarded by the Council the Gold Medal of the Association in recognition of his distinguished work for the Association and the profession. Dr Bone was given a great ovation.

Sir Hugh Lett, the Past President, invested Lady Whitby with the President's Lady's Badge, remarking that one seldom heard

a really great man speak of his work without paying a tribute to the help he had received from his wife. Those who knew Sir Lionel Whitby were well aware how true this was in his case. Lady Whitby said a few graceful words in acknowledgment.

Next came the presentation of the Association prizes. Some of the prizewinners were unable to be present, but the following received their prizes at the hands of the President:

Dr J. G. Nathan (Stoke-on-Trent), the Sir Charles Hastings Clinical Prize.

Mr A. Hedley Visick (York), First Prize in the Nathaniel Bishop Harman Award.

Dr W. Hedley Summerskill (Southsea), Second Prize in the Nathaniel Bishop Harman Award.

The following prizes were awarded to nurses for the best essays on certain prescribed subjects:

Pupil Nurses:

First Prize—Miss P. Yates, Queen Elizabeth Hospital, Birmingham.

Second Prize—Miss Monica M. Pearce, General Hospital, Birmingham.

State Registered Nurses working in a hospital:

First Prize—Miss Joyce Donaldson, Little Bromwich Hospital, Birmingham.

Second Prize—Miss Lois Beulah, Queen Mary's Maternity Home, London, NW3.

State Registered Nurses not working in a hospital, district nurses, private nurses, etc:

First Prize—Mrs A. J. Franklin, Deganwy, Caernarvonshire.

Second Prize—Miss N. Mackintosh, West Lothian.

The President then delivered his address, entitled "The Changing Face of Medicine." The address was published in the *Journal* of July 3. Thanks to excellent loud speaker arrangements every word was heard perfectly in all parts of the hall.

At the close, Dr E. A. Gregg, Chairman of the Representative Body, expressed the thanks of the assembly to the President. He said that if the visitors had come to Cambridge for nothing else than to hear this address their visit would have been well worth while. They would carry away from Cambridge many happy memories, of generous hospitality, of inspiring meetings, of noble buildings, but he was sure the outstanding impression would be one associated with this very fine and instructive address.

After the proceedings in the Senate House were over an adjournment was made to Old Schools, almost adjoining, for the President's reception. Sir Lionel and Lady Whitby received about 700 guests.

## PROCEEDINGS OF COUNCIL

Monday, June 28

A meeting of the Council was held in the Small Examination Hall, Bene't Street, Cambridge, on June 28. Dr H. Guy Dain presiding.

The congratulations of the Council were conveyed to twenty-five members of the Association whose names appeared in the recent Honours List.

The Council heard with regret of the illness of Dr James Fenton, chairman of the Public Health Committee, and sent him a message of sympathy.

On the proposition of the Chairman it was resolved unanimously and with acclamation to award to Dr J. W. Bone at the conclusion of his Treasurership the Gold Medal of the Association for his distinguished services to the Association and to the profession.

Dr Dain and Dr Gregg were appointed delegates to represent the Association at the General Assembly of the World Medical Association, to be held in Geneva in September. It was mentioned that Dr J. A. Pridham was attending the assembly in another capacity.

Mr A. M. A. Moore presented a report from the Consultants and Specialists Committee. This opened up the consideration

of the Specialist Spens Report. The Consultants and Specialists Committee could not approve the principle of granting awards for merit which was put forward in the Spens recommendations, and had passed certain expressions of opinion to the Negotiating Committee.

The Council noted the views of the Committee on this subject, and it was understood that the newly constituted committee would look further into the subject and bring it forward again before Council.

Dr R. G. Gordon, for the Science Committee, brought forward recommendations for awards of Association prizes and scholarships which were approved. He said that the essay competition for nurses had evoked an excellent response, and though the quality of the entries was uneven the committee had no hesitation in recommending prizes, six in number, with commendations to six other entrants.

The Council, on the recommendation of the Office Committee, accepted the invitation of the Medical Association of South Africa to hold an Annual Meeting in Johannesburg in 1951.

Dr Bone, in presenting for the last time the report of the Finance Committee, said that the great feature of the first four months of this year was the remarkable increase in income, but the commitments of the Association were also extending.

It was agreed that the Treasurer be authorized at his discretion to permit payment of expenses of travel by air of members attending central meetings, provided that the member could establish his claim to this payment in virtue of special circumstances.

It was reported that an initial step had been taken towards the establishment of regional offices for the Association. Certain office premises had been taken in Leeds, and similar arrangements were being made at Cambridge.

Dr Janet Aitken, for the Committee on the Care and Treatment of the Elderly and Infirm, presented a memorandum entitled "The Right Patient in the Right Bed," which is a supplement to the earlier report of the Committee. The report was approved for publication, and it was agreed that copies should be sent to the chief officers of the regional hospital boards, hospital management committees, and local authorities.

Routine reports by the Industrial Medicine Committee and the Welsh Committee were approved. On the motion of Mr Moore it was agreed to open negotiations with the appropriate authorities to secure the application with retrospective effect, of the recommendations of the Inter-Departmental Committee on the Remuneration of Consultants and Specialists to full-time medical teachers and laboratory and research workers.

Various matters were held over for the first meeting of the new Council.

Wednesday, June 30

The first meeting of the new Council was held in the Small Examination Hall, Cambridge, on Wednesday morning, June 30.

Nominations were invited for the chairmanship, and from many parts of the Council it was moved that Dr H. Guy Dain be re-elected. He was called unanimously to the Chair, and in thanking the members said that he had now been chairman for a number of years and thought it was time for a change. In view of the wish expressed, however, he was prepared to carry on for a further year, but that must be the limit.

The several new members of the Council were then welcomed—namely, Dr C. W. Curtis Bain (President-elect), Dr J. Cottrell, Dr J. A. Gorsky, Dr I. G. Innes, Dr W. M. Knox, Air Commodore J. Kyle, Dr R. P. Liston, Dr J. C. Pearce, Major-General Sir Percy Tomlinson, Dr H. Vickers, and, in his absence, Lord Horder.

It was agreed that there was no occasion to take a referendum on any of the decisions of the Annual Representative Meeting.

Dr S. J. Hadfield was appointed an Assistant Secretary of the Association in place of Dr Revans, who had resigned.

A letter was read from Lord Webb-Johnson, of Stoke-on-Trent, thanking the Council for its congratulations on his elevation to the peerage, and stating that he would at all times do his utmost to co-operate with the Association in promoting the welfare of medicine.

In accordance with the decision of the Representative Body a Special Committee was appointed to consider the effectiveness of the Association in collective bargaining and the best method by which it would be obtained. It was agreed that the Committee should consist of the principal officers of the Association, the chairmen or their nominees of the General Practice, Insurance Acts, Central Consultants and Specialists, Scottish, Ethical, and Organization Committees, and five other members—namely, Dr J A Brown, Mr L Dougal Callander, Dr O C Carter, Dr F Gray, and Dr J A Gorsky.

The Council proceeded to the election of members to Standing and Special Committees. At its previous meeting the Council had agreed that the immediate postgraduate training of the general practitioner should be a special subject of study and a committee of 26 members was appointed for this purpose.

The Protection of Practices Committee and six other special committees, having discharged their reference, were not re-appointed. The number of special committees to which members were appointed was twenty, and in addition members were appointed to five joint committees with other organizations. Dr J A Ireland and Dr F Gray were appointed representatives of the Association on the Council of the Society of Medical Officers of Health.

The consideration of a long report by the Health Centre Committee had been deferred from the last meeting of the old Council, but it was felt that members of Council, especially the new members—had not yet had time to study the document, and, as the matter was considered to be of some urgency inasmuch as certain local authorities were said to be preparing plans for such centres, it was agreed to hold a special meeting of Council for the consideration of this report on July 14.

The proceedings then terminated.

## RECEPTIONS AT CAMBRIDGE

The abounding hospitality of Cambridge manifested itself in a number of receptions, some of them informal and sectional, but three for the general body of members and their ladies attending the Annual Meeting. The first of these was the reception given by the Vice-Chancellor of the University the Rev Canon C E Raven. This was held at Christ's College, of which the Vice-Chancellor is Master. The guests were received by the Vice-Chancellor in his lodgings, and tea was served in the great hall. The guests were shown round the historic College including the Fellows' Building, built in the middle of the seventeenth century, and also saw the beautiful gardens, freshened by recent rain, with the mulberry tree associated with the most famous of Christ's men—John Milton. The reception offered a welcome relaxation in a day filled with business and official functions.

On the same evening, following the President's Address in the Senate House, a reception was given in Old Schools, almost adjoining 'Standing in the Dome Room, Sir Lionel and Lady Whitby received many hundreds of guests, until the old building, large as it is, could hardly accommodate another. With the red and black gowns of the doctors, the jewels and orders and the evening dresses of the ladies, the scene was animated and picturesque, and Old Schools provided the ideal setting. Part of the building goes back to the late fourteenth century, and much of it to the fifteenth. From the Dome Room, which is an eighteenth-century addition, the guests proceeded to the Council Room, which housed the first University Library, and then to Regent House the University's oldest building, originally used as chapel and senate house.

On the following evening, again at Old Schools, the Association enjoyed civic hospitality. The Mayor and Mayoress (Councillor and Mrs G F Hickson) received a large number of guests. An interesting feature of this reception was the exhibition of the ancient charters of Cambridge as well as other treasures of the town, including the maces. The great mace is of silver gilt, weighing 155 oz, and dates from the reign of Queen Anne, each of the four smaller maces, also of silver gilt, weighs between 80 and 90 oz. Another interesting Corporation exhibit was a small copper gilt sergeant's mace which was used in the reign of Charles I, and probably purposely mutilated at the death of the King. Music and conversation prolonged the proceedings to a late hour.

## ANNUAL DINNER OF THE ASSOCIATION

The dinner in connexion with the Annual Meeting at Cambridge was held on Thursday evening July 1, and was attended by about 600 members and guests. The President (Sir Lionel Whitby) occupied the Chair and was supported by the principal officers of the Association. Among the distinguished guests were the Lord-Lieutenant of Cambridgeshire (Capt R G Briscoe), the Vice-Chancellor of the University (Rev C E Raven, D.D.), the Mayor of Cambridge (Councillor G F Hickson), the Master of Trinity (Dr G M Trevelyan), and Major-Gen E A Noyes, representing the American Medical Association.

### "The University and Town of Cambridge"

Sir Hugh Lett, Immediate Past-President, reminded the assembly that the first provincial meeting after the first World War was also held at Cambridge. This was no mere coincidence. There were great ties between Cambridge and the medical profession, and there could be no better place in which to begin afresh.

There was another reason for coming to Cambridge—namely, the close association between Cambridge and the medical profession which had continued for 400 years since Dr John Caius did so much for the University and Medicine. John Caius was a great liaison officer: he was President of the Royal College of Physicians for nine years, he wrote a textbook in English and he introduced the study of anatomy into Cambridge. On this point he would say a word on behalf of the "down-trodden surgeons." There was an extraordinary veneration for physicians in Cambridge yet John Caius owed a great deal to the surgeons, because when he came back after his wanderings he was given a job by the Barber-Surgeons Company the forerunner of the Royal College. Because of this John Caius had the opportunity of practising dissection in the only place in England in which it was allowed, and from that one could trace his institution of the study of anatomy in Cambridge.

He wished to say how much the Association appreciated all that had been done by the University and the town through the Vice-Chancellor and the Mayor to make its stay as happy as possible. It would have been observed that "University and Town" were combined in a single toast. In the old days there was keen rivalry between town and gown. But the one could not get on without the other, the University would be in great difficulties without the town, and the town would not be what it was without the University, so that it was appropriate to ask the company to join him in a comprehensive 'health act,' and he was sure it would be welcomed without the slightest difficulty.

The Vice-Chancellor, in responding for the University, said that Winston Churchill was not the only one to receive a degree at the hands of the Chancellor on the recent occasion, and he was proud that the toast had been proposed by the newest Honorary Graduate, a very distinguished surgeon and successor to Dr John Caius. He would summarize the very long speech he had prepared in three headings. First, the "crimes" of the University against medicine in the form of the anatomy paper, how any human being survived that memory test had always been to him a miracle. That it created a dislike of surgery he had not the slightest doubt and he thought it created a certain dislike of anatomy which remained even to this day. This "crime" had been repented of and to some extent expiated. The second "crime," unfortunately still existing, was that men reading for medicine could not come to Cambridge until they had read the first M.B. This was a crime of the greatest magnitude, because it condemned the student to specialization at far too early an age. Next there were the benefits of medicine to the University, the University had been in dispute with Government circles on the question of salaries, but the findings of the Spens Committee would be a great help on this question.

In spite of these crimes and benefits there remained a relationship with a long history, with a splendid present, and a still more splendid future, when Cambridge had its new regional hospital and school, with the possibility of completing medical training in Cambridge, other parts of the kingdom would have to look to their laurels. The University owed the Association

a deep debt of gratitude for holding its conference in Cambridge and wished it well.

The Mayor of Cambridge said he was a mere layman in this scientific gathering, but he had listened with great interest to the President's Address although it contained some technical phraseology. He did not need technical language to thank Sir Hugh Lett for his kind words in proposing the toast. Cambridge had been very pleased to see this first big conference since before the war, it was most appropriate that a learned body should come to Cambridge, and he hoped the Association would not wait until there was another world war before it came again.

#### "The British Medical Association"

Dr G M Trevelyan (Master of Trinity) proposed the toast of the Association. He said he was qualified for his task only by the admiration he had always felt for the sort of person a doctor usually was, and by the fact that he had many close friends among the medical profession. He had lived a long and very healthy life out of the hands of the doctors. One of his dearest friends was Sir Walter Morley Fletcher, a man of the widest culture, with a wonderful zest for everything good in life, who was the first secretary of the Medical Research Council, and the great work accomplished by that institution was largely due to the impetus given it by its first secretary. It was not only because of the men of science and of academic distinction that he admired the profession. Living as he did in a remote district of Cumberland for part of the year, he had seen the devoted work of the doctor and what an isolated community owed to his willing, zealous, sympathetic help and care. There was a spirit of service which no private fees nor State salary could buy. He wished that all other sections of the community had that spirit to the same extent as the doctors, and as a historian he knew what a great and indispensable part doctors had played in building up our present civilization and modern organization which enabled nearly 50 million people to live in this little island.

Cambridge was not uninterested in the progress of medical science, Cambridge folk were specially delighted by the choice of President this year, and he hoped his Address would be read far and wide. It was a great honour to propose the toast of the British Medical Association.

The Chairman of Council (Dr H Guy Dain) asked how he could reply to such a toast without bigging, it was quite impossible. The British Medical Association was a voluntary association of doctors to preserve their honour and interests. The days of increased specialization had separated doctors into little cliques and had given them different functions which did not always seem to hold very well together, but who would hold them together if not the British Medical Association?

The Association had this year achieved what had never been done before in this country or in any other, it had organized or modified the organization of a health service in which the freedom of the people and of the doctors was preserved. Without the Association's strenuous efforts that would not have been attained. The public were now free to choose their doctor, the doctor was free to go into the Service or stay out, he was free to say what he liked about medicine or the Service without supervision. He was free to practise under the conditions which hold today, with very little limitation, and his success in life would depend on the goodwill of the patient.

These features having been attained, a Service was about to commence such as had never before existed. Other countries had tried them and had made one mistake or another, these had been avoided and, now that the struggle was over and freedom had been obtained, doctors would put their best efforts into making it a really fit and proper and good Service for the people of this country.

The Association was determined to see that this was done, that the honour and interest of the medical profession was upheld and having attained freedom, he would remind his hearers that the price of freedom was eternal vigilance. That would be the work of the British Medical Association.

#### "The Guests"

Alderman Dr Robert Ellis in a short speech proposing the health of the guests, said that no function in Cambridge was complete without the Lord-Lieutenant of the County, the Chair-

man of the County Council, the Vice-Chancellor, and the Mayor, all of whom were present. He also welcomed those who had come from all parts of the Empire and from countries with kindred associations throughout the world. Some had come to Cambridge for the first time, others were making its acquaintance after a long interval, and he was certain they would return to their homes with happy memories of their stay in Cambridge this week.

The Lord Lieutenant of Cambridgeshire (Capt R G Briscoe), in response said that he had always found individual members of the profession most entertaining, but he had always had to pay for the entertainment, that night, however, he and all the other guests had been entertained for nothing, and for that he would say "Thank you." As Lord Lieutenant he would like to welcome the medical profession to the county, and as a prospective patient to placate them.

Dr V H L Anthonisz, OBE (Ceylon), also in response said that he came from the newest Dominion overseas but not the least loyal in the great British Commonwealth of Nations. In his Dominion the medical service was entirely State controlled, and it was a great pleasure to be present on the eve of the birth of the new National Health Service, as it would be to watch its growth, development, and future achievements. He had been pleased and delighted with the wonderful entertainment and generosity which had been extended to his wife and himself and appreciated the privilege of attending the meeting. He wished the new Health Service every success.

Mayor C A Noyes, MC, MD (American Medical Association), in a brief reply, extended on behalf of his own Association best wishes and congratulations on the 116th Annual Meeting. He trusted that the cordial and helpful associations and relationship which had been existing between the American Medical Association and the British Medical Association would continue to grow and flourish in the years to come.

#### "The President"

Prof E D Adrian, OM, MD, FRCP, FRS, said that when Sir Lionel Whitby was appointed to Cambridge they knew that the Crown could do no wrong, but it was gratifying to find out how very right it could be. It had given Cambridge someone eminent both in the scientific and practical side of medicine, he was a man who could get things done. He was an admirable Chairman of the Faculty Board, and he would be an admirable President, and every member was grateful to him for agreeing to lead them in these difficult times.

Sir Lionel Whitby said it was very difficult to reply to a toast proposed to oneself. There was a great difference between having something to say and having to say something, but at least he could say "Thank you" for the way in which the toast had been received and "Thank you" to Prof Adrian for the way in which he proposed it. He would add that any success at this meeting was in very large part due to the tremendous assistance he had had from his many auxiliaries, secretaries, and others, and he had enjoyed it very much.

## THE EXHIBITION OF SURGICAL INSTRUMENTS AND DRUGS

The exhibition of surgical instruments and appliances, drugs, foods, and other products of medical interest which was a feature of pre-war Annual Meetings, reappeared at Cambridge, and if not quite as large, was as interesting as ever. Many applications for space had to be refused owing to the limited accommodation, but the very best use was made of the sixty stands which were available and the housing of the Exhibition, which was in the Guildhall, in the centre of the town and close to the places of meeting was all that could be desired.

The Exhibition was opened on the morning of June 29 by Sir Lionel Whitby the President of the Association. He congratulated the organizers on the splendid way in which the Exhibition had been set up. It was the first BMA exhibition of the kind for nine years. It included, he said, exhibits of the finest products on the manufacturing side of medicine. For many years this country had had reason to be proud of the way in which medicine was served by the manufacturers of fine

chemicals and pharmaceutical products, by the makers of surgical instruments and orthopaedic appliances, and by others whose skill and ingenuity were directed to the production of tools and material for the physician and surgeon. These manufacturers had endeavoured to deliver nothing but the best for the service of the medical profession. Many firms had spent a great deal of time and money on research and in that way had made a notable contribution to the advance of medicine. Sir Lionel Whitby mentioned the work on salvarsan, the development of the sulphonamides and the production of antimalarial drugs as examples of manufacturing enterprise in these fields. There was good friendship and co-operation between the profession and the manufacturers which was to their mutual benefit as well as to the benefit of a third party, most important of all—namely, the patients.

The meeting of the Representative Body was put back in order to give representatives an opportunity to inspect the exhibits.

## OVERSEAS CONFERENCE

A conference of representatives from Overseas Branches was held at Cambridge on June 30. Mr J. L. Gilks, FRCS, chairman of the Dominions Committee, presided.

The Secretary (Dr Charles Hill) made a statement on the Empire Medical Advisory Bureau and the projected Commonwealth Medical Council. So far as the Dominions were concerned, the Council of the Association thought that the time had come to establish a body which was in a sense superior to the medical associations or branches in the Dominions, the idea being that regarding Great Britain as itself a Dominion on terms of equality with the other Dominions, there should be established a Dominion Medical Council consisting at the outset of three representatives of each Dominion. The meeting in this first year would be in London. Practically all the Dominions were members of the World Medical Association, which would hold its assembly in Geneva in September, and the Dominions Conference would be held in London the week following. The invitation had been accepted with alacrity by practically every Dominion. It was hoped that this Conference would effect a liaison between the Dominions on terms of complete equality.

The establishment of a special organization to have as its main purpose the giving of advice on all problems—professional, social and other—which confronted men coming to this country for the first time was the result of another decision of the Council. The Association had set aside £5,000 a year for this purpose. The committee of management of the Empire Medical Advisory Bureau was presided over by Sir Hugh Lett. At the back of their minds was the hope that an increasing number of overseas practitioners would come to this country for postgraduate instruction, and this Bureau would do all it could to assist them. On the subject of conditions of service in the Colonial Medical Service, Dr Hill said that the next task in the negotiations on remuneration would be to secure the acceptance of the Spens recommendations on remuneration of general practitioners and specialists for all other groups of medical practitioners. This would include the Colonial Medical Service.

Dr H. A. Sandiford, director of the Bureau, gave a few additional details. The Bureau, he said, would be opened on July 13. The service would include the making available of information concerning facilities for postgraduate study, the maintenance of a register of lodgings and hotels, the supply of a wide range of general information, arrangements for private hospitality, and the bringing together of overseas practitioners and prominent members of the profession in this country. It was hoped eventually to arrange for practitioners from the Dominions and Colonies to be met at the ports.

Dr E. Grey Turner, Assistant Secretary at Headquarters in charge of the work of the Dominions Committee, gave a review of the work of the committee during the year and also said it had been suggested by one overseas visitor that the new Bureau should have a two-way action, not only advising practitioners coming from overseas but also British practitioners going out to the Empire. Already any doctor who was going to any part of the world was welcomed at B.M.A. House and

given such information as was available. Concerning the terms of service for Colonial medical officers, the Chairman of Council had made it plain at the Representative Meeting that the negotiation of the terms of service for practitioners in the National Health Service in Britain would be followed by a full endeavour to bring the remuneration of other services, including the Colonial Medical Service, into alignment. In the meanwhile the Colonial Office had been urged to make an interim improvement in rates of pay.

Dr J. Gow (Victoria) and other overseas delegates showed a desire for information about the exact position in Great Britain and in particular what occurred between the two plebiscites, and on request Dr Hill gave an account of recent events.

Dr J. N. P. Davies (Uganda) suggested that the Association might set up an office at which practitioners when going overseas could get information about their contracts. Dr Davies also, in view of the proposed Annual Meeting in Johannesburg in 1951, suggested that members who went by air should make a stop at Kampala where the Uganda Branch would organize a meeting and afford what entertainment it could. Dr F. J. Wright (Kenya) suggested similarly that a stop be made at Nairobi. Dr Wright also proposed that when the various medical services were running in parallel their terms and conditions being based on the Spens Reports, it might be possible for the Association to arrange transfers from one service to another without loss of pension rights. Dr Hill said that interchange of superannuation rights would be one of the points to be discussed.

Dr J. Cauchi (Malta), Dr G. Fraser (Northern Bengal) and other representatives raised various points and an informal discussion ensued.

## THE CHURCH SERVICE

The official religious service in connexion with the Annual Meeting was held in Great St. Mary's Church, Cambridge, on the afternoon of June 29. Members robed in the Examination Hall, Bene't Street, and with the President and principal officers at their head, proceeded to the church across Market Hill. Other processions were those of the Vice-Chancellor and of the Mayor who was accompanied by the Mayoress and members of the Corporation. The service was conducted by the Vicar of Great St. Mary's, the Rev. G. E. A. Whitworth, and the sermon was preached by the Lord Bishop of Ely, the Rt. Rev. H. E. Wynn, D.D. The first lesson was read by the Chairman of Council and the second lesson by the President. A collection was taken on behalf of medical charities.

In his sermon the Bishop of Ely addressed himself to the co-operation of the minister of religion and the doctor. He said that physicians and surgeons in the course of their work must often have asked themselves whether it was worth while in the best sense of the words, to keep some of their patients alive. Their duty was clear and they had followed it, but perhaps sometimes they doubted its wisdom. Thanks to the advance of medical knowledge, they were able to heal the body far more completely than in the past, but no one could say that the restoration was to what was described in the New Testament as a 'perfect soundness'. The body might be healed, but the mind, the character, the personality, the soul might still be mortally sick. He knew from a wide personal experience that many physicians and surgeons went beyond the healing of the body. These men were rightly loved and respected, but they would be the first to say that they had neither the time nor the training nor, it might be, the knowledge to do that work properly.

'It is here,' the Bishop continued, 'that we perceive the need for closer co-operation between the physician and the minister of God. Not indeed, that there is no co-operation at present. That is far from the truth. But it needs to be closer and there must be a fuller mutual understanding. You will note that I do not say "between the Church and the medical profession" for that might imply that the medical profession is one organization and the Church another. The Church embraces all Christian believers and whatever work any of us is doing is work for Christ and His Church. But

a deep debt of gratitude for holding its conference in Cambridge and wished it well

The Mayor of Cambridge said he was a mere layman in this scientific gathering, but he had listened with great interest to the President's Address although it contained some technical phraseology. He did not need technical language to thank Sir Hugh Lett for his kind words in proposing the toast. Cambridge had been very pleased to see this first big conference since before the war, it was most appropriate that a learned body should come to Cambridge, and he hoped the Association would not wait until there was another world war before it came again.

#### "The British Medical Association"

Dr G M Trevelyan (Master of Trinity) proposed the toast of the Association. He said he was qualified for his task only by the admiration he had always felt for the sort of person a doctor usually was, and by the fact that he had many close friends among the medical profession. He had lived a long and very healthy life out of the hands of the doctors. One of his dearest friends was Sir Walter Morley Fletcher, a man of the widest culture with a wonderful zest for everything good in life who was the first secretary of the Medical Research Council, and the great work accomplished by that institution was largely due to the impetus given it by its first secretary. It was not only because of the men of science and of academic distinction that he admired the profession. Living as he did in a remote district of Cumberland for part of the year, he had seen the devoted work of the doctor and what an isolated community owed to his willing, zealous, sympathetic help and care. There was a spirit of service which no private fees nor State salary could buy. He wished that all other sections of the community had that spirit to the same extent as the doctors, and as a historian he knew what a great and indispensable part doctors had played in building up our present civilization and modern organization which enabled nearly 50 million people to live in this little island.

Cambridge was not uninterested in the progress of medical science, Cambridge folk were specially delighted by the choice of President this year, and he hoped his Address would be read far and wide. It was a great honour to propose the toast of the British Medical Association.

The Chairman of Council (Dr H Guy Dain) asked how he could reply to such a toast without bragging, it was quite impossible. The British Medical Association was a voluntary association of doctors to preserve their honour and interests. The days of increased specialization had separated doctors into little cliques and had given them different functions which did not always seem to hold very well together, but who would hold them together if not the British Medical Association?

The Association had this year achieved what had never been done before in this country or in any other, it had organized or modified the organization of a health service in which the freedom of the people and of the doctors was preserved. Without the Association's strenuous efforts that would not have been attained. The public were now free to choose their doctor, the doctor was free to go into the Service or stay out, he was free to say what he liked about medicine or the Service without supervision, he was free to practise under the conditions which hold to day, with very little limitation, and his success in life would depend on the goodwill of the patient.

These features having been attained a Service was about to commence such as had never before existed. Other countries had had them and had made one mistake or another, these had been avoided and now that the struggle was over and freedom had been obtained, doctors would put their best efforts into making it a really fit and proper and good Service for the people of this country.

The Association was determined to see that this was done, that the honour and interest of the medical profession was upheld and having attained freedom he would remind his hearers that the price of freedom was eternal vigilance. That would be the work of the British Medical Association.

#### "The Guests"

Alderman Dr Robert Ellis in a short speech proposing the health of the guests, said that no function in Cambridge was complete without the Lord-Lieutenant of the County, the Chair-

man of the County Council, the Vice Chancellor, and the Mayor, all of whom were present. He also welcomed those who had come from all parts of the Empire and from countries with kindred associations throughout the world. Some had come to Cambridge for the first time, others were making its acquaintance after a long interval, and he was certain they would return to their homes with happy memories of their stay in Cambridge this week.

The Lord-Lieutenant of Cambridgeshire (Capt R G Briscoe), in response said that he had always found individual members of the profession most entertaining, but he had always had to pay for the entertainment, that night, however, he and all the other guests had been entertained for nothing, and for that he would say "Thank you". As Lord Lieutenant he would like to welcome the medical profession to the county, and as a prospective patient to placate them.

Dr V H L Anthonisz, OBE (Ceylon) also in response said that he came from the newest Dominion overseas but not the least loyal in the great British Commonwealth of Nations. In his Dominion the medical service was entirely State-controlled and it was a great pleasure to be present on the eve of the birth of the new National Health Service as it would be to watch its growth, development, and future achievements. He had been pleased and delighted with the wonderful entertainment and generosity which had been extended to his wife and himself and appreciated the privilege of attending the meeting. He wished the new Health Service every success.

Major E A Noyes MC, MD (American Medical Association), in a brief reply, extended on behalf of his own Association best wishes and congratulations on the 116th Annual Meeting. He trusted that the cordial and helpful associations and relationship which had been existing between the American Medical Association and the British Medical Association would continue to grow and flourish in the years to come.

#### "The President"

Prof E D Adrian, OM, MD, FRCP, FRS said that when Sir Lionel Whitby was appointed to Cambridge they knew that the Crown could do no wrong, but it was gratifying to find out how very right it could be. It had given Cambridge someone eminent both in the scientific and practical side of medicine, he was a man who could get things done. He was an admirable Chairman of the Faculty Board, and he would be an admirable President, and every member was grateful to him for agreeing to lead them in these difficult times.

Sir Lionel Whitby said it was very difficult to reply to a toast proposed to oneself. There was a great difference between having something to say and having to say something, but at least he could say "Thank you" for the way in which the toast had been received and "Thank you" to Prof Adrian for the way in which he proposed it. He would add that any success at this meeting was in very large part due to the tremendous assistance he had had from his many auxiliaries, secretaries, and others, and he had enjoyed it very much.

## THE EXHIBITION OF SURGICAL INSTRUMENTS AND DRUGS

The exhibition of surgical instruments and appliances, drugs, foods, and other products of medical interest which was a feature of pre-war Annual Meetings, reappeared at Cambridge, and if not quite as large, was as interesting as ever. Many applications for space had to be refused owing to the limited accommodation but the very best use was made of the sixty stands which were available and the housing of the Exhibition, which was in the Guildhall, in the centre of the town and close to the places of meeting was all that could be desired.

The Exhibition was opened on the morning of June 29 by Sir Lionel Whitby the President of the Association. He congratulated the organizers on the splendid way in which the Exhibition had been set up. It was the first BMA exhibition of the kind for nine years. It included, he said exhibits of the finest products on the manufacturing side of medicine. For many years this country had had reason to be proud of the way in which medicine was served by the manufacturers of fine

chemicals and pharmaceutical products by the makers of surgical instruments and orthopaedic appliances and by others whose skill and ingenuity were directed to the production of tools and material for the physician and surgeon. These manufacturers had endeavoured to deliver nothing but the best for the service of the medical profession. Many firms had spent a great deal of time and money on research and in that way had made a notable contribution to the advance of medicine. Sir Lionel Whitby mentioned the work on salvarsan, the development of the sulphonamides and the production of antimalarial drugs as examples of manufacturing enterprise in these fields. There was good friendship and co-operation between the profession and the manufacturers which was to their mutual benefit as well as to the benefit of a third party—most important of all—namely, the patients.

The meeting of the Representative Body was put back in order to give representatives an opportunity to inspect the exhibits.

## OVERSEAS CONFERENCE

A conference of representatives from Overseas Branches was held at Cambridge on June 30. Mr J. L. Gills, FRCS, chairman of the Dominions Committee, presided.

The Secretary (Dr Charles Hill) made a statement on the Empire Medical Advisory Bureau and the projected Commonwealth Medical Council. So far as the Dominions were concerned the Council of the Association thought that the time had come to establish a body which was in a sense superior to the medical associations or branches in the Dominions, the idea being that regarding Great Britain as itself a Dominion on terms of equality with the other Dominions there should be established a Dominion Medical Council consisting at the outset of three representatives of each Dominion. The meeting in this first year would be in London. Practically all the Dominions were members of the World Medical Association which would hold its assembly in Geneva in September, and the Dominions Conference would be held in London the week following. The invitation had been accepted with alacrity by practically every Dominion. It was hoped that this Conference would effect a liaison between the Dominions on terms of complete equality.

The establishment of a special organization to have as its main purpose the giving of advice on all problems—professional, social and other—which confronted men coming to this country for the first time was the result of another decision of the Council. The Association had set aside £5,000 a year for this purpose. The committee of management of the Empire Medical Advisory Bureau was presided over by Sir Hugh Lett. At the back of their minds was the hope that an increasing number of overseas practitioners would come to this country for postgraduate instruction, and this Bureau would do all it could to assist them. On the subject of conditions of service in the Colonial Medical Service Dr Hill said that the next task in the negotiations on remuneration would be to secure the acceptance of the Spens recommendations on remuneration of general practitioners and specialists for all other groups of medical practitioners. This would include the Colonial Medical Service.

Dr H. A. Sandiford, director of the Bureau, gave a few additional details. The Bureau, he said, would be opened on July 13. The service would include the making available of information concerning facilities for postgraduate study, the maintenance of a register of lodgings and hotels, the supply of a wide range of general information, arrangements for private hospitality, and the bringing together of overseas practitioners and prominent members of the profession in this country. It was hoped eventually to arrange for practitioners from the Dominions and Colonies to be met at the ports.

Dr E. Grey Turner, Assistant Secretary at Headquarters in charge of the work of the Dominions Committee, gave a review of the work of the committee during the year and also said it had been suggested by one overseas visitor that the new Bureau should have a two-way action, not only advising practitioners coming from overseas but also British practitioners going out to the Empire. Already any doctor who was going to any part of the world was welcomed at B.M.A. House and

given such information as was available. Concerning the terms of service for Colonial medical officers, the Chairman of Council had made it plain at the Representative Meeting that the negotiation of the terms of service for practitioners in the National Health Service in Britain would be followed by a full endeavour to bring the remuneration of other services, including the Colonial Medical Service, into alignment. In the meanwhile the Colonial Office had been urged to make an interim improvement in rates of pay.

Dr J. Gowland (Victoria) and other overseas delegates showed a desire for information about the exact position in Great Britain and in particular what occurred between the two plebiscites and on request Dr Hill gave an account of recent events.

Dr J. N. P. Davies (Uganda) suggested that the Association might set up an office at which practitioners when going overseas could get information about their contracts. Dr Davies also, in view of the proposed Annual Meeting in Johannesburg in 1951, suggested that members who went by air should make a stop at Kampala, where the Uganda Branch would organize a meeting and afford what entertainment it could. Dr F. J. Wright (Kenya) suggested similarly that a stop be made at Nairobi. Dr Wright also proposed that when the various medical services were running in parallel their terms and conditions being based on the Spens Reports, it might be possible for the Association to arrange transfers from one service to another without loss of pension rights. Dr Hill said that interchange of superannuation rights would be one of the points to be discussed.

Dr J. Cauchi (Malta), Dr G. Fraser (Northern Bengal), and other representatives raised various points, and an informal discussion ensued.

## THE CHURCH - SERVICE

The official religious service in connexion with the Annual Meeting was held in Great St. Mary's Church, Cambridge, on the afternoon of June 29. Members robed in the Examination Hall, Bene't Street, and with the President and principal officers at their head, proceeded to the church across Market Hill. Other processions were those of the Vice-Chancellor and of the Mayor, who was accompanied by the Mayoress and members of the Corporation. The service was conducted by the Vicar of Great St. Mary's, the Rev. G. E. A. Whitworth, and the sermon was preached by the Lord Bishop of Ely, the Rt. Rev. H. E. Wynn, D.D. The first lesson was read by the Chairman of Council, and the second lesson by the President. A collection was taken on behalf of medical charities.

In his sermon the Bishop of Ely addressed himself to the co-operation of the minister of religion and the doctor. He said that physicians and surgeons in the course of their work must often have asked themselves whether it was worth while in the best sense of the words, to keep some of their patients alive. Their duty was clear, and they had followed it, but perhaps sometimes they doubted its wisdom. Thanks to the advance of medical knowledge, they were able to heal the body far more completely than in the past, but no one could say that the restoration was to what was described in the New Testament as a "perfect soundness." The body might be healed, but the mind, the character, the personality, the soul might still be mortally sick. He knew from a wide personal experience that many physicians and surgeons went beyond the healing of the body. These men were rightly loved and respected, but they would be the first to say that they had neither the time nor the training nor, it might be, the knowledge to do that work properly.

It is here," the Bishop continued, "that we perceive the need for closer co-operation between the physician and the minister of God. Not indeed, that there is no co-operation at present. That is far from the truth. But it needs to be closer and there must be a fuller mutual understanding. You will note that I do not say 'between the Church and the medical profession' for that might imply that the medical profession is one organization and the Church another. The Church embraces all Christian believers, and whatever work any of us is doing is work for Christ and His Church. But

## H.M. Forces Appointments

### ROYAL NAVY

Acting Surgeon Lieutenants T J Scannell, H Walters, and N Watson to be Surgeon Lieutenants

### ROYAL NAVAL VOLUNTEER RESERVE

Surgeon Lieutenant G McI Forsyth to be Surgeon Lieutenant Commander

Temporary Acting Surgeon Lieutenants D G L Davies, P Jordan J D Montagu, K M Backhouse, W T Miller, P K Ledger, J S Rawlins, P R Clay, W V Graham, and W A Watt to be Temporary Surgeon Lieutenants

### ROYAL ARMY MEDICAL CORPS

Lieutenant Colonel S W Burrows has retired on retired pay and has been granted the honorary rank of Colonel

Captains (War Substantive Majors) D H D Burbridge and G R Marshall DSO to be Majors

Captains A M Buchanan, L R Taylor, and I W Caldwell to be Majors

*Short Service Commissions*—Captain T Bird has retired receiving a gratuity and has been granted the honorary rank of Major

Captain W J Christie, from Emergency Commission, to be Captain

### TERRITORIAL ARMY

#### ROYAL ARMY MEDICAL CORPS

Captains J H Richmond and T L Oliver to be Majors

Lieutenant E S Curtiss to be Captain, and has been granted the acting rank of Major

Lieutenant H T H Arnott from T A R O, Army Cadet Force (Warwick), to be Lieutenant

### LAND FORCES EMERGENCY COMMISSIONS

#### ROYAL ARMY MEDICAL CORPS

Captain (Honorary Major) C R Harris has been re-employed in the rank of Captain, without pay and allowances, and has been granted the unpaid temporary rank of Major

War Substantive Captain J H Sturatt has relinquished his commission and has been granted the honorary rank of Major

D N Parfitt to be Lieutenant without pay and allowances and has been granted the unpaid temporary rank of Lieutenant Colonel

*Short Service Commission Specialists*—War Substantive Captains W J Ferguson R J Carr H M Goldberg, and A Naylor have relinquished their commissions and have been granted the honorary rank of Major Captain J Corbett has relinquished his commission and has been granted the honorary rank of Captain

### WOMEN'S FORCES

#### EMPLOYED WITH THE R A M C

Lieutenants M Staunton and B B Noone to be Captains

## AGENTS DETERMINING AND INFLUENCING THE FUNCTIONS OF THE PARS NERVOSA OF THE PITUITARY\*

BY

E B VERNEY, F.R.S., F.R.C.P.

*Professor of Pharmacology University of Cambridge*

The pars nervosa of the pituitary is essentially the macroscopic representation of the multiple and terminal branching of axons most of which originate from the supraoptic nuclei. These nuclei are bilaterally placed in the ventral surface of the anterior part of the hypothalamus, each is separated into an anterior and posterior division by the emergence of the optic tract from the optic chiasma, and the axons stream thence as the supraoptico-hypophyseal tracts in the antero-ventral wall of the infundibulum, to their distribution in the pars nervosa. The structural entity comprising the nuclei, tracts, and pars nervosa is called the neurohypophysis. Extracts of the pars nervosa exhibit antidiuretic, oxytocic and, under certain experimental conditions, pressor and diuretic properties and I propose in this opening paper to confine consideration to the first of these by briefly reviewing the evidence which has led to the endowment of this pharmacological property with the significance of a physiological function.

### Conditions Leading to Profuse Watery Diuresis

There are three conditions under which a profuse watery diuresis is observed and in each instance the effect of posterior pituitary extract is to reduce the rate of water

and thirdly the administration by mouth of large volume of water to the living mammal.

The effects of post-pituitary extract on the polyuria associated with the first condition are closely simulated by switching into the perfusion circuit, in parallel with the kidney, the head of a dog the inhibition of diuresis and

Fig. 1—Inhibitory responses to intracarotid injection of hypertonic solution during water diuresis in the dog: *a* at 4 injection of 10 ml of 1.50% NaCl into left carotid in 10 seconds; *b* at 7 injection of 11 ml of 1.50% NaCl into right carotid in 12 seconds. Abscissae: time after the test dose of water.

output by the kidney and to increase the percentage of chloride in the urine. These conditions are first perfusion of the dog's kidney in the isolated state, secondly experimental or pathological lesions of the neurohypophysis.

\* Read in opening a discussion in the Section of Pharmacology at the Annual Meeting of the British Medical Association, Cambridge.

Fig. 2—Responses to injections *a* and *b* 5 days before *c* and *d* 11 days after removal of posterior lobe of pituitary: *a* at 4 injection of 21 ml of 2.50% NaCl into right carotid in 20 seconds; *b* at 4 1 mU of post-pituitary extract injected intravenously in 15 seconds; *c* at 4 injection of 21 ml of 2.50% NaCl into right carotid in 20 seconds; *d* at 4 0.1 mU (curve C) and 0.2 mU (curve D) post-pituitary extract injected intravenously in 20 seconds. Abscissae: time (approx) after the test dose of water.

increased excretion of chloride being then dependent upon the presence of the pituitary in the perfused head and these effects may occur without appreciable diminution of blood flow through the kidney at constant perfusion pressure. The view was put forward therefore that the phenomenon of profuse watery diuresis exhibited by the kidney perfused in the isolated state was due to the divorce of the kidney from the inhibitory influence of the antidiuretic substance elaborated in the pars nervosa.

This view has received strong support from observations made under the second of the conditions to which I have just referred—viz., experimental or pathological lesions of the neurohypophysis. The chequered aetiological history

## AGENTS DETERMINING AND INFLUENCING THE FUNCTIONS OF THE PARS NERVOSA OF THE PITUITARY\*

BY

E B VERNEY, FRS, FRCP

*Professor of Pharmacology University of Cambridge*

The pars nervosa of the pituitary is essentially the macroscopic representation of the multiple and terminal branching of axons most of which originate from the supraoptic nuclei. These nuclei are bilaterally placed in the ventral surface of the anterior part of the hypothalamus, each is separated into an anterior and posterior division by the emergence of the optic tract from the optic chiasma and the axons stream thence, as the supraoptico-hypophyseal tracts in the antero-ventral wall of the infundibulum, to their distribution in the pars nervosa. The structural entity comprising the nuclei, tracts, and pars nervosa is called the neurohypophysis. Extracts of the pars nervosa exhibit antidiuretic, oxytocic, and, under certain experimental conditions, pressor and diuretic properties and I propose in this opening paper to confine consideration to the first of these by briefly reviewing the evidence which has led to the endowment of this pharmacological property with the significance of a physiological function.

### Conditions Leading to Profuse Watery Diuresis

There are three conditions under which a profuse watery diuresis is observed, and in each instance the effect of posterior pituitary extract is to reduce the rate of water

and thirdly the administration by mouth of large volumes of water to the living mammal.

The effects of post-pituitary extract on the polyuria associated with the first condition are closely simulated by switching into the perfusion circuit, in parallel with the kidney, the head of a dog the inhibition of diuresis and

FIG. 1—Inhibitory responses to intracarotid injection of hypertonic solution during water diuresis in the dog: *a* at 4 injection of 10% ml of 1.50% NaCl into right carotid in 9 seconds; *b* at 11 ml of 1.50% NaCl into right carotid in 13 seconds. Abscissae: time after the test dose of water.

output by the kidney and to increase the percentage of chloride in the urine. These conditions are first perfusion of the dog's kidney in the isolated state; secondly experimental or pathological lesions of the neurohypophysis.

\*Read in opening discussion in the Section of Pharmacology Annual Meeting of the British Medical Association, Cambridge 1947.

FIG. 2—Responses to injections: *a* and *b* 5 days before *c* and *d* 11 days after removal of posterior lobe of pituitary: *a* at 4 injection of 21 ml of 2.50% NaCl into right carotid in 20 seconds; *b* at 1 mU of post-pituitary extract injected intravenously in 15 seconds; *c* at 4 injection of 21 ml of 2.50% NaCl into right carotid in 20 seconds; *d* at 0.1 mU (curve C) and 0.2 mU (curve D) post-pituitary extract injected intravenously in 20 seconds. increased excretion of chloride being then dependent upon the presence of the pituitary in the perfused head, and these effects may occur without appreciable diminution of blood flow through the kidney at constant perfusion pressure. The view was put forward, therefore, that the phenomenon of profuse watery diuresis exhibited by the kidney perfused in the isolated state was due to the divorce of the kidney from the inhibitory influence of the antidiuretic substance elaborated in the pars nervosa.

This view has received strong support from observations made under the second of the conditions to which I have just referred—viz, experimental or pathological lesions of the neurohypophysis. The chequered aetiological history

FIG 3—The injections were made at the arrow. The corresponding changes in urine chloride are given by the curves at the bottom of the figure. Abscissae: time after the test dose of water.

the diabetes insipidus associated with these has culminated in the elegant demonstration by Ranson and his colleagues that the occurrence of diabetes insipidus is contingent upon the complete or quasi-complete degeneration or removal of the neurohypophysis. Using the Horsley-Clarke stereotaxic instrument, they have been able to place small discrete lesions at any desired points in the hypothalamus and to show that when by these means the supraoptico-hypophysial tracts are interrupted a series of striking degenerative changes takes place in the supraoptic nuclei and in the neural division of the hypophysis, the degeneration being associated with a fall of some 95% in antidiuretic activity as measured by comparative assays of extracts of the normal and of the atrophic pituitaries. The view, therefore, that diabetes insipidus derives essentially from a deficiency complete or extreme, in the antidiuretic product of the neurohypophysis would appear, on the available evidence, to be incontrovertible.

The third condition under which a profuse watery diuresis appears is the administration of water by mouth to the living mammal, and the question arises whether this phenomenon, too, is of pituitary origin. When water is given by stomach-tube to the dog under conditions which, both externally and internally, are kept as constant as possible, the diuretic responses to successive doses are sufficiently uniform to allow analysis of the phenomenon's underlying events. That such responses are not so simply determined as appearance suggests is shown by the fact that the course of alimentary absorption is well in advance of that of renal excretion, there being in the dog under certain experimental conditions, an interval of 15 minutes between the peak of the water-load—i.e. the proportion of absorbed but as yet unexcreted water—and the peak of diuresis. The significance of this interval will be considered later. The response of the innervated kidney runs strictly parallel with

that of the denervated kidney, and the response is unaccompanied by any change in the volume flow of blood through the kidney.

#### Inhibition of Diuresis Response

Next, this diuresis response may be inhibited in various ways—for example, by subjecting the animal to short-lived muscular exercise or to emotional stress and by intravenous injections of adrenaline or of post-pituitary extract. The inhibition produced by short periods of muscular exercise in the dog—e.g., running at 6 m.p.h. for 4 minutes—has been shown to be due to the emotional accompaniment of the exercise, and, since the inhibition from emotional stress was very much like that produced by an intravenous dose of post-pituitary extract, it seemed worth while to analyse the phenomenon with some care. The induced emotional disturbance need be a very small one, an unfamiliar and ugly sound being sometimes enough to elicit

an inhibitory response. Usually, however, a weak faradic current carried to the subcutaneous tissues by surgically clean needle electrodes, as being a simpler and more controllable form of stimulus, has been used for the analysis of the resultant inhibition. From such analysis we now know that the inhibition of water diuresis by emotional stress is independent of the nerve supply to the kidney, is not caused by the endogenous release of adrenaline, is unaccompanied by any appreciable change in the volume flow of blood through the kidney, and is deferred by some two minutes from the time of the stimulus. The inhibition of water diuresis by the intravenous injection of post-pituitary extract likewise shows all these characteristics and with a suitable dose of extract the response to the one agent is indistinguishable from that to the other.

So close a resemblance between the two responses both in form and in measurable accompaniments and independencies, made one confident that removal of the posterior lobe of the pituitary would be followed by a big reduction in the inhibitory response to emotional stress. This was found experimentally to be so. There can, then, be little doubt that the stimulus produces the observed changes in the excretion of water and chloride by ultimate involvement of the supraoptic group of hypothalamic cytons whose axons pass down the stalk of the pars nervosa, and by whose activity the pituitary antidiuretic substance is released. Certain pharmacological agents, too, affect the functional activities of the neurohypophysis.

#### A Controlling Factor

The demonstration in the normal animal of the release of pituitary antidiuretic substance by the artificial means of faradic stimulation of sensory nerves and receptors, and the fact that this release may be caused by such mild disturbance of the central nervous system as comes within

a physiological range encouraged an attempt to determine whether the secretion of this substance was not continuously varying with and under the direct control of some factor in the animal's internal environment, to the maintenance of which factor within a narrow physiological range the renal excretion of water and of chloride would specifically contribute. Such a factor is clearly the osmotic pressure of the arterial blood and it became of interest to determine the effects of a rise in this pressure on the secretion of the kidney during water diuresis.

For this purpose dogs have been provided with carotid loops whereby injections or infusions may be made direct into the common carotid blood stream. While intracarotid injection of isotonic solution of sodium chloride and intravenous injection of hypertonic solutions are without apparent action on the course of water diuresis, intracarotid injection of hypertonic solutions causes definite inhibitory responses. They are illustrated in Fig 1. The shape of these responses suggested that they were of pituitary origin, and this hypothesis was put to the test of experiment by measuring the response to a given injection before and after removal of the posterior lobe. Fig 2a gives the response to 21 ml of 2.50% NaCl injected into the right carotid in 20 seconds, and we may note in passing that it equates closely with the response to 1 mU of post-pituitary extract injected intravenously (Fig 2b).

The response to the same intracarotid injection after removal of the posterior lobe is given in Fig 2c: it is very much reduced in size. It is therefore a valid procedure to assay the responses in terms of post-pituitary extract and when this is done it is found that the response to a given intracarotid injection is diminished by some 90% as the result of removal of the posterior lobe. Fig 2d gives the response to an intravenous injection of 0.1 mU

#### Action of Sodium Chloride

It now became important to know whether the sodium chloride was acting specifically or by virtue of the increase which it produced in the osmotic pressure of the plasma. To this end equal increases in the osmotic pressure of the carotid blood were produced by injections of sodium chloride, sodium sulphate, dextrose, and urea. While the responses to sodium chloride and sodium sulphate were indistinguishable, the response to dextrose was seemingly little smaller, suggesting that the osmotic effectiveness of dextrose was less than that of the other two solutes. Urea, on the other hand, was found to be quite inactive. A similar comparison was then made between the effects of osmotically identical injections of sodium chloride and sucrose. The results are given in Fig 3. Three responses are shown: two of them (black circles and squares) are to injection of the sodium chloride solution, and the third (open circles) is to the injection of the sucrose solution. The calculated percentage increases in the osmotic pressure of the carotid blood during the injections are 52 and 53

FIG 4—The rectangle 1 covers the period of the infusions. Abscissa: time (approx) after the last dose of water.

respectively. The response to sucrose lies between the two responses to sodium chloride. Moreover the courses of the concentration of chloride in the urine (shown at the bottom of the figure) are identical. Seeing that the only common and equal change in property of the carotid blood caused by the injection of these two solutions is the increase in osmotic pressure and that both produce quantitatively the same release of post-pituitary antidiuretic substance the osmotic determination of the phenomenon is beyond cavil.

#### Osmoreceptors

It becomes justified therefore to introduce the term "osmoreceptors" as descriptive of the autonomic receptive elements with which the neurohypophysis is functionally linked and through whose activation the pituitary antidiuretic substance is released, and the facts so far presented show that when they are exposed to short-lived and large increases in the osmotic pressure of their environment their "membrane" is relatively impermeable to sodium chloride, sodium sulphate and sucrose, less impermeable to dextrose and freely permeable to urea.

Where then do these receptors lie? They are not in the carotid sinus nor in the carotid body. Comparison of the effects of like increases in the osmotic pressure of the common carotid blood before and after ligation of the internal carotid artery, however, has shown that such ligation virtually abolishes the response. The receptors lie therefore in the vascular bed normally supplied by the

FIG 5—Effect of 40 minute infusion of NaCl into the carotid and the method of its assay. The black rectangle covers the period of the infusions. With the intracarotid infusion the calculated local increase in osmotic pressure is 18%. Abscissae time (approx) after the test dose of water.

internal carotid artery. Their precise location and histological identification must be left to future experimentation.

So far we have been considering the responses of the osmoreceptors to short-period (10 to 20 seconds) and large (50 to 100%) increases in the osmotic pressure of their environment. It now became of interest to determine the effects of exposure of the receptors to much smaller increases maintained over longer periods. For this purpose intravascular infusions of various solutes have been made at uniform rates over periods of 10 and 40 minutes. It was found that when over a period of 10 minutes a hypertonic solution of sodium chloride was infused into a carotid the inhibition of urine flow occurred earlier than when the same infusion was made into the malleolar vein, and that as the strength of the infused solution was reduced this difference became greater. The cause of the earlier onset of the inhibition when the infusion was made into the carotid must be attributed to the increase in osmotic pressure of the internal carotid blood over and above that of the aortic blood.

This difference between the effects of intracarotid and intravenous infusions is illustrated in Fig 4. During the 10-minute period shown by the black rectangle a sodium chloride was being introduced into the circulation at the rate of 1 mg/sec. The effect of this procedure on the course of the urine flow when the infusion was made into the right carotid is shown by the black circles, when into the malleolar vein by the open circles. The third curve (black-and-white circles) shows that the response to the intracarotid infusion is closely matched when to the intravenous infusion is added post-pituitary extract in such amount that 1.67  $\mu$ U is being introduced into the circula-

tion every second. The calculated local increase in osmotic pressure produced by the intracarotid infusion is 54%. Comparable experiments with sodium sulphate and with sucrose gave results which on assay were closely similar to those of the sodium chloride experiments. With dextrose, however, two striking differences appeared: there was a small response to the intravenous infusion, and the response to the intracarotid infusion, though larger than that to the intravenous, was definitely smaller than that to an osmotically equivalent infusion of sodium chloride. The osmoreceptors therefore are, under these conditions, at least partially permeable to dextrose.

#### Long-period Intracarotid Infusion

We come now to the effects of a much smaller increase in the osmotic pressure of the carotid blood maintained over a much longer period—viz, 40 minutes. The results obtained with infusions of sodium chloride at 0.33 mg/sec are illustrated in Fig 5. The black rectangle covers the period of the infusions. With the intracarotid infusion (curve A, black circles) the urine flow, after a latent period of some 10 minutes, begins to fall, eventually it reaches the low rate of 0.5 ml/min, at which level the flow is persisting when the infusion is stopped. The flow then slowly increases, to reach a rate of nearly 4 ml/min thirty minutes later. The intravenous infusion (curve E), on the other hand, has no appreciable influence on the course of the diuresis. The calculated percentage increase in the osmotic pressure of the carotid blood during the intra-arterial infusion is 18, corresponding with a local increase in blood chloride of 9 mg/100 ml, and the experiment shows that under these conditions the "membrane" of the osmoreceptors maintains its relative or complete impermeability to sodium chloride for a period of at least 40 minutes.

In strictly comparable experiments with dextrose, however, no difference was detected between the effect of the intracarotid and that of the intravenous infusion. With the intracarotid infusion the local increase in blood dextrose responsible for the 18% increase in osmotic pressure is some 90 mg/100 ml, the conclusion is justified, therefore, that the "membrane" of the osmoreceptors is permeable to dextrose to such degree that a maintained rise in blood dextrose of some 90 mg/100 ml—a rise which, incidentally, is within the human pathological range—fails to elicit an antidiuretic secretory response by the neurohypophysis. *Patients with diabetes mellitus are still permitted to be polyuric.* When similar experiments were made with sucrose the results of the intracarotid infusions showed

close quantitative agreement with those obtained with sodium chloride. The assay of such response to sodium chloride is illustrated in Fig 5. The response to the intra-carotid infusion (black circles) lies for most of its course between the responses to 0.67 (black-and-white circles) and 1.17 (open circles)  $\mu\text{U}/\text{sec}$ , being nearer to and probably a little less than the latter—it is assayed as having a post-pituitary-extract equivalence of 1  $\mu\text{U}/\text{sec}$ .

#### Conclusions from Results of Long-period Infusions

Three conclusions follow from the results of the 40-minute infusions. First, that increases in the osmotic pressure of the arterial blood—increases which, when large, were shown by the short-period injections to release post-pituitary antidiuretic substance—are still operative when they are reduced to values well within a range which may reasonably be regarded as physiological. An increase of only 1.8% in the osmotic pressure of the carotid blood gradually reduces the rate of urine flow from a water-diuresis maximum to the sort of rate which prevails at the beginning and end of a normal response to ingested water—i.e., a reduction of some 90%. The smallness of the osmotic pressure increase gains additional interest when it is recollected that the intra-carotid infusions were unilateral. For if, as is probable, only half of the total number of osmoreceptors are being exposed under these conditions to the osmotic pressure increment, an increase of some 1% only (54 mm Hg in absolute terms) in the osmotic pressure of the aortic blood would suffice to produce the same degree of inhibition of urine flow—i.e., a reduction to about 10% of the maximum rate of which the kidney is capable during water diuresis.

Secondly, the results of the 40-minute infusions demonstrate that the induced change in the osmotic pressure of the arterial blood which is responsible for this degree of reduction in urine flow itself causes the release of post-pituitary antidiuretic substance at an average rate of 1  $\mu\text{U}/\text{sec}$  ( $0.5 \times 10^9$  g/sec in terms of the standard powder), this being the intermediating agency through which the change in osmotic pressure becomes effective.

Thirdly, the recovery of urine flow when the intra-carotid infusion is stopped (Fig 5) shows that the secretion of post-pituitary antidiuretic substance is now inhibited by the local fall in osmotic pressure and consequent depression of activity in the osmoreceptors, the progression of this recovery being attributable to the gradual destruction in the kidney, and maybe in the blood, of the quantity of antidiuretic substance which was maintaining the secretion of urine at a non-diuretic level. The latent period between the peak of the water-load curve and the maximum rate of urine secretion, to which I referred earlier and promised to return is clearly to be attributed to the same process.

Water diuresis, then, is fitly and accurately described as a condition of physiological diabetes insipidus, and there can be little doubt that the antidiuretic secretion of the neurohypophysis is a hormone in the physiological sense that its liberation is mainly and continually governed by the contemporary concentration of sodium chloride in the carotid arterial plasma. The physiological fitness of this control is emphasized by its quantitative aspects, in that changes within the range and of the order of 1% in the osmotic pressure of the arterial blood lead, through the intermediation of the antidiuretic hormone, to changes in the rate of water excretion within the range and of the order of 1,000%—the maintenance of near constancy in the osmotic pressure of the internal environment is thereby achieved.

## THE USE OF POST-PITUITARY EXTRACT IN PHYSIOLOGICAL AMOUNTS IN OBSTETRICS

### A PRELIMINARY REPORT

BY

G. W. THEOBALD, M.D., F.R.C.S.D., F.R.C.O.G.

A. GRAHAM, M.B., Ch.B.

W. J. DRISCOLL, M.B., B.Ch.

(From the Obstetric Unit St. Luke's Maternity Hospital  
Bradford)

In 1895 Oliver and Schafer reported that extracts made from the pituitary gland caused a rise of blood pressure in anaesthetized animals when injected intravenously. Three years later Howell (1898) demonstrated that their pressor activity was confined to the posterior lobe, and this was confirmed in the following year by Schafer and Vincent. In 1901 Schafer and Magnus reported that post-pituitary extract exerted both diuretic and antidiuretic activities, and it was not until 1915 that Konschegg and Schuster first demonstrated that in conscious animals only an antidiuretic response could be obtained. Dale in 1906, was the first to draw attention to the fact that this extract stimulated uterine muscle, and this activity was confirmed in 1909 by Frankl-Hochwart and Frohlich.

It is now generally accepted that post-pituitary extract contains two active principles: (a) a pressor which is identical with the antidiuretic activity and (b) an oxytocic substance. Both principles are destroyed by heat, trypsin digestion, hydrochloric acid decomposition, and alkaline hydrolysis, and both are of approximately the same molecular size. Further, in the most purified extracts the pressor and oxytocic activities remain in the same proportions as in an ordinary post-pituitary extract. It was for these reasons that for many years controversy raged on whether post-pituitary extract contained one or more active principles and it was not until 1928 that Kamm *et al.* settled the dispute by separating and concentrating two active principles in the form of potent solid preparations.

In 1925 a Committee of the League of Nations adopted the USP Standard Reference Powder as the international standard, 0.5 mg of this powder being equivalent to one international unit. The international standard preparation of the post-pituitary gland is simply a powder made from the whole posterior lobes of cattle, collected immediately after death and ground in acetone in order to remove water and fat. The different standard powders may therefore differ somewhat in activity, but it is unlikely that the discrepancy ever exceeds 20% in either direction. Until 1928 post-pituitary extracts were standardized for their oxytocic activity by a method devised by Dale and Laidlaw in 1912, but the separation of two distinct principles by Kamm *et al.* suggested the desirability of devising a separate method for assaying the pressor activity of these extracts.

Blair Bell was the first to use post-pituitary extract in obstetric practice, and in 1909 he reported its efficacy in the treatment of post-partum haemorrhage and intestinal atony. It is of interest to note that before this date no clinical application of

\*Mr Gange terminated his appointment as resident obstetric officer at the end of December, 1947.

We are greatly indebted to the Director of the Department of Biological Standards, the National Institute for Medical Research, Hampstead, for the above information.

post-pituitary extract had been made other than to prescribe tablets by mouth for their supposed diuretic activity. Two years later Hofbauer (1911) suggested its use in the treatment of uterine inertia. In 1927 Bourne and Burn concluded "that valuable application of a dose of 2 units can be made in cases in which labour is prolonged owing to sluggish pains provided that in primiparae dilatation is nearing completion". There is still however, a widespread fear, based on unfortunate happenings of using post-pituitary extracts until labour is completed. Reid (1946) and Eastman (1947) have recently advocated the use of small amounts of post-pituitary extract in cases of prolonged labour. Reid advocates starting with one minim (0.06 ml) and increasing the dosage to not more than five minims (0.3 ml) whereas Eastman is more cautious and starts with a half minim (0.03 ml), and never gives more than one minim. Both authors consider it wise to confine this method of treatment to obstetrically normal primigravidae whose progress in labour is tedious.

In 1931 Burn described a method of estimating the anti-diuretic activity of post-pituitary extract by injecting it subcutaneously into a number of rats. This method was accurate within certain limits, but the subcutaneous route of injection introduced unknown, uncalculable and avoidable errors. Using the method described by Khsiecki *et al* (1933), one of us (Theobald, 1934a, 1934b) showed that the intravenous injection of from 0.0005 to 0.01 unit of infundin\* inhibited water diuresis not only in the dog but also in man, and in women during the last few weeks of pregnancy. The amount of anti-diuretic activity necessary to inhibit water diuresis was remarkably constant for each dog, and the water diuresis curves thus inhibited, obtained over a period of several months, could be almost superimposed. Later in the same year Bentz, Marx and Schneider (1934) and Stehle (1934) also showed that very small amounts of post pituitary extract, when injected intravenously inhibited water diuresis in the dog.

Two conclusions may be drawn from these results. The first is that, contrary to the observation of Kamm *et al* the anti-diuretic activity affords the most delicate and possibly the most accurate method of assaying post pituitary activity. The second is that the post-pituitary gland elaborates the two active substances in remarkably constant proportions (a fact observed by many workers), for it will be noted that infundin is standardized for its oxytocic activity. It was for this reason that it has always seemed to us logical to assume that the normal physiological oxytocic responses in the body are effected by an amount of the oxytocic principle of the same order as that of the anti-diuretic principle which inhibits water diuresis.

For the same reasons one of us has postulated (Theobald 1934b) that the post-pituitary gland does not elaborate a pressor principle, but that the anti-diuretic principle when injected intravenously in many thousand times its physiologically effective amount, happens to exert a transient pressor effect. Further, several observers have reported that post-pituitary extract constricts the coronary vessels, while Leschke (1919) has stated that it causes sino-auricular block, and these concomitant effects can hardly be regarded as desirable or likely to accompany the activity of a physiological pressor substance. We are not aware that Verney has specifically stated that it is illogical to assume that Nature would provide the same substance both to elevate the blood pressure and to inhibit water diuresis when it is evident that many thousand times the amount adequate for the one activity is required to effect the other but it is clearly implicit in his writings (Verney, 1947).

### Clinical Observations

We have addressed ourselves to two main problems (1) the induction of labour, and (2) the stimulation of uterine pains in cases of uterine inertia.

The procedure was as follows. Either 9 or 19 ml of 5% glucose-saline was placed in a small sterile bowl and to it 1 ml of pituitrin† was added and stirred. The requisite amount

of this mixture was then added to a standard bottle containing 500 ml of a 5% glucose-saline solution prepared for intravenous injection. The dilutions of the pituitrin drip we have used have been 1 in 2,500, 1 in 5,000, and 1 in 10,000. Whereas for some months we used the 1 in 2,500 solution almost exclusively, we now prefer either the 1 in 5,000 or the 1 in 10,000 solution. It may be that the ideal lies in between the last two strengths. There is some reason to believe that the 1 in 2,500 solution occasionally causes irregularity of the foetal heart. In addition to the pituitrin we have sometimes added quinine bihydrochloride 2 gr (0.13 g), carbachol 25 mg, and 100-200 mg of pethidine to the bottle of glucose saline. The drip was set up in the ordinary manner, using a vein in either the arm or leg and the infusion was begun at a standard rate of 40 drops to the minute. This rate was decreased if the pains became too strong or too frequent, and was occasionally increased. Not more than three bottles were given on any one day but the drip was often discontinued and restarted on the following day.

### Induction of Labour

It was felt that if a safe, efficient, and reasonably rapid method of inducing labour at any time during the last three weeks of pregnancy could be devised it would be of distinct value in obstetrics. It can be stated that, so far, the pituitrin drip, even when quinine and carbachol were added, proved a quite unreliable method of terminating pregnancy, and failed more often than it succeeded.

We found that the most effective single method of inducing labour was to sweep the membranes from that part of the lower uterine segment immediately above the internal os uteri with the finger and to touch this denuded area lightly with the silver stick. Labour supervened within 24 hours in the first 11 cases, but subsequent experience showed that the method was not always successful.

The routine to which we adhere at present is composite. In the first instance, four doses of quinine sulphate 10 gr (0.65 g) are given at four-hourly intervals. Two ounces (57 ml) of castor oil are given either just before or just after the third dose of quinine. A copious warm enema is administered approximately four hours after the castor oil. If the woman does not go into labour within 24 hours from the time that the quinine induction is completed the membranes are ruptured at a point immediately below the presenting part. Should she not go into labour during the next 24 hours the pituitrin drip is started.

During the first three months of this year 43 patients were subjected to this method of induction of labour. Twenty-two went into labour within 24 hours of the completion of the quinine therapy, the membranes were ruptured in 20 cases and the pituitrin drip was administered in 9 cases. In one of these the pituitrin drip was given 24 hours after the completion of the quinine therapy. The membranes of this patient were not ruptured, because she showed a marked degree of pelvic contraction. All the infants, save one a breech delivery were born alive and survived. One of us (G. W. T.) has used the quinine method of induction in hundreds of cases, we are satisfied that it is a safe way to induce labour, and it is successful in between 50 and 60% of all cases at term. The intervals between the administration of quinine must not be less than four hours, and the drug must be withheld once uterine contractions begin. In our experience any other form of medical induction is comparatively unsuccessful.

Only two patients caused anxiety, and they were both elderly obese multigravidae. Subsequent labour was in each case associated with marked uterine inertia. One was a 5-gravida, aged 35, with hypertension, who had not been pregnant for some years and was overdue, the other was a 6-gravida, aged 45, whose first pregnancy had terminated by caesarean section and whose youngest child was 6 years old. In each case delivery was effected by a difficult forceps extraction. The infant of the former patient died as the result of cerebral haemorrhage.

A number of patients were admitted after spontaneous rupture of the membranes. In our experience labour may be delayed subsequent to the rupture of the membranes for as many as eight days, and this delay may be associated with intra-uterine death of the foetus. In these cases a pituitrin drip, containing in addition quinine hydrochloride 2 gr (0.13 g) in

\*A commercial preparation of post-pituitary extract made by Messrs Burroughs, Wellcome and Co., and standardized for its oxytocic content.

†A commercial preparation of post-pituitary extract made by Messrs Parke Davis and Co., and standardized for its oxytocic content.

bottle of glucose saline solution, is set up. The drip is run down after two or three bottles have been administered recommenced next day. Whereas the drip may have no apparent effect on the first day, it usually happens that uterine contractions occur within one to ten minutes of restarting the drip on the following day.

It is our practice to rupture the membranes whenever possible in the treatment of placenta praevia and to apply a tight binder. In three recent cases labour did not supervene within the course of the next 20 hours, so the pituitrin quinine drip was begun. In one case labour pains started almost immediately, while in the other two it had to be repeated next day. All these babies were born alive and well.

### Primary Uterine Inertia

We first treated cases of primary uterine inertia by the pituitrin drip method in June 1947, and propose to report the results obtained in 20 consecutive cases treated during the last 5 months. In all one of these patients had previously given birth to a full term living child *per vias naturales* and she was a 5-gravida who had previously been delivered by caesarean section and she had had two miscarriages and a premature infant which died. Of the 20 patients four were aged 40 years or over and nine were over 30 years (three being 38 years old). In all cases the head was free above the brim, and in only four was the head fully engaged. One was a breech presentation. After 'trial labours' two were delivered by caesarean section. The patients were delivered by the forceps, and the remaining nine delivered themselves spontaneously. One baby died from a nuchal tear. The largest infant weighed 9 lb (4.08 kg), and the average weight was 7 lb 6 oz (3.34 kg).

### Case Reports

**Case 1 Placenta Praevia**—D.M., aged 23, 1-gravida, term 16 1947—Admitted because of ante-partum haemorrhage, in labour Nov 17—7 p.m. Cervix two fingers dilated, vaginal placenta praevia, membranes ruptured, Willett's forceps applied to control bleeding 9.30 p.m. Weak pains at five minute intervals. Nov 18—1 a.m. Weak pains every 15 minutes 3 a.m. Pains 9.30 a.m. Still no pains 10.10 a.m. Pituitrin 1 in 500 + quinine 2 gr (0.13 g) drip begun 10.20 a.m. Slight short in 10.30 a.m. Moderate pains every three minutes, drip stopped, 3 pint (190 ml) given 12.40 p.m. Cervix fully dilated 1.30 p.m. Delivery of living female child weighing 7 lb 8 oz (3.4 kg) 4.8 p.m. Placenta and membranes expelled complete.

**Case 2 Induction of Labour**—E.H., aged 23, 2-gravida term previous elective caesarean section for contracted pelvis associated with transverse lie Sept 30 1947—12.30 a.m. membranes ruptured 1 a.m. Admitted to hospital, transverse lie, no pains, draining liquor amni, lie changed to vertex by external manipulation pads and binder applied 7 p.m. Still no pains—head free, pituitrin 1 in 2,500 + quinine 2 gr drip 7.45 p.m. Vague pains—one every 20 minutes 9 p.m. Moderate pains every five minutes, head engaging 10 p.m. Second bottle started 11 p.m. Head on perineum, drip discontinued Oct 1—17 a.m. Spontaneous delivery of living male child weighing 7 lb 7 oz (2.92 kg).

**Case 3 Induction of Labour**—A.S. aged 31, 1-gravida 8 1947—11 a.m. Membranes ruptured June 9—7 p.m. Admitted to hospital, no pains 8 p.m. Head engaging, os two fingers dilated, B.P. 130/70 mm Hg 8.35 p.m. 1 in 5,000 pituitrin drip started (30 drops a minute) 11.35 p.m. Pains every 5 minutes fairly strong, os two fingers dilated drip slowed to 20 drops a minute, pot brom and chloral hydrate 30 gr (2 g) June 10—5 a.m. Os fully dilated 2.10 a.m. Spontaneous delivery of living female child, 6 lb 5 oz (2.86 kg).

**Case 4 Induction of Labour Uterine Inertia**—M.H., aged 1-gravida, 38 weeks Sept 8 1947—Admitted with hyperemesis Sept 17—11.50 a.m. Pituitrin 1 in 2,500 + quinine 2 gr drip started (three bottles given) Sept 18—5.30 p.m. Pains began 7.10 p.m. Membranes ruptured 7.10 p.m. Moderate pains every 10 minutes, head engaged, os two fingers dilated 8.40 p.m. Pains every four minutes—strong os two to three fingers dilated, atropine 150 mg and hyoscine 1/100 gr (0.65 mg) given 10 p.m. Progress Sept 19 12.40 a.m. Strong pains every three minutes, os three fingers dilated 1.15 p.m. Pituitrin 1 in 5,000 + quinine 1 gr (65 mg) drip started, B.P. 155/110 mm Hg 4 p.m. Needle out of vein, drip discontinued, indefinite pains 4 p.m. Second bottle of pituitrin + quinine drip started 5 p.m. Moderate pains every four minutes 6 p.m. Mild rigor 6.40 p.m. Pains every four minutes 8.30 p.m. Strong pains every 10 minutes os three to four fingers dilated 10.50 p.m. Only

rim of cervix palpated, pethidine 100 mg given Sept 20—5.20 a.m. Forceps delivery of living female child 7 lb 10 oz (3.46 kg).

**Case 5 Induction of Labour Uterine Inertia**—C.G., aged 21, 1-gravida Nov 26 1947—Membranes ruptured spontaneously during the night Nov 27—5.15 p.m. Admitted to hospital Nov 28—10 a.m. No pains, no obvious loss of liquor amni 3.50 p.m. Draining much liquor amni, no pains 9.5 p.m. Foetal heart 120, irregular, no pains 11.10 p.m. Pituitrin 1 in 2,500 + quinine 2 gr drip started 11.15 p.m. B.P. 104/60 mm Hg, no pains Nov 29—12.10 a.m., no pains 12.40 a.m. Pot brom and chloral hydrate 30 gr (2 g) given 1 a.m. Second bottle of pituitrin drip started 2.45 a.m. Weak pains every 10 minutes 3.30 a.m. Third bottle started 5.10 a.m. Drip discontinued, foetal heart 120, regular, castor oil 2 oz (57 ml) given, followed four hours later by enemata 10.10 a.m. Fairly strong pains every five minutes head free, os one finger dilated 2.10 p.m. Moderate pains every 10 minutes, head free 7.35 p.m. Pelvis contracted, but no obvious disproportion, pot brom and chloral hydrate 30 gr given Nov 30—12.15 a.m. Weak pains, pot brom and chloral hydrate 30 gr given 12.45 a.m. Pains repeated at 2 a.m. 10.50 a.m. Slept well, no pains, head still free, liquor amni blood-stained 11.45 a.m. Pituitrin 1 in 2,500 + quinine 2 gr drip started, B.P. 104/60 mm Hg, pains started immediately uterine spasm, drip slowed for 10 minutes 12.15 p.m. Strong pains every three minutes, foetal heart rate 136 12.45 p.m. Needle out of vein 1.45 p.m. Drip restarted, head engaging, os two fingers dilated 2 p.m. Strong pains every three minutes, pot brom and chloral hydrate 30 gr 2.20 p.m. Pethidine 100 mg and hyoscine 1/150 gr (0.433 mg) given 3.45 p.m. Well sedated 6.15 p.m. Third bottle started, strong pains every three minutes head still palpable above brim 6.30 p.m. Drip discontinued 7 p.m. Head showing at vulva 7.10 p.m. Spontaneous delivery of living female child, 6 lb 1 oz (2.75 kg).

**Case 6 Uterine Inertia**—A.B., aged 43, 5-gravida, 39 weeks Feb 14 1948—5.10 a.m. Membranes ruptured 12 midnight Labour started Feb 15—6 a.m. Admitted to hospital head free, cervix closed, pains moderate Feb 16—10 a.m. Head entering pelvic inlet, cervix one finger dilated, pains weak 4.30 p.m. Pains stronger, every two to three minutes 5.15 p.m. Cervix one finger dilated, morphine 1/4 gr (16 mg), scopolamine 1/100 gr (0.65 mg), nembuto 1 1/2 gr (0.1 g) 6.15 p.m. Pituitrin drip 1 in 10,000 begun, B.P. 108/80 mm Hg 6.55 p.m. Pains stronger 8 p.m. Pains strong, cervix two fingers dilated, B.P. 110/80 mm Hg 10 p.m. Pains strong, head descending, cervix 3/4 dilated, drip stopped 10.45 p.m. Precipitate delivery of living child.

**Case 7 Uterine Inertia Incision of Cervix**—L.S., aged 31, 1-gravida, term Nov 20 1947—Admitted at 9.30 p.m. from a nursing home with history of having started labour at 9 p.m. on Nov 16 and membranes having ruptured at 5 a.m. on Nov 17. On admission the head was well engaged, os one finger dilated, B.P. 145/100 mm Hg. Morphine 1/4 gr was given immediately. Nov 21—7 a.m. Irregular pains at approximately ten-minute intervals 2.30 p.m. Moderately strong pains every three minutes, pethidine 100 mg 3.30 p.m. Pethidine 100 mg 8 p.m. Strong pains every five minutes 11.45 p.m. Pethidine 200 mg given 12 midnight Pituitrin 1 in 2,500 + quinine 2 gr drip started, B.P. 140/100 mm Hg Nov 22—12.45 a.m. Pains every seven minutes, B.P. 140/100 mm Hg 2 a.m. Strong pains every five minutes 2.5 a.m. Pethidine 100 mg given 4 a.m. Pains still strong, no change in position of head, os two fingers dilated 9.30 a.m. Drip discontinued 11 a.m. Has slept well since 5 a.m., condition good 1.20 p.m. Cervix incised and living female child weighing 8 lb (3.63 kg) delivered with forceps. Post-partum haemorrhage controlled with ergometrine.

This patient was in labour for nearly six days, and although the cervix became thinned out it failed to become more than half dilated in spite of fairly good pains.

**Case 8 Uterine Inertia**—M.L., aged 38, 1-gravida, term Jan 9 1948—11.30 p.m. Admitted to hospital, membranes having ruptured Jan 10—12 noon Vague uterine contractions, head free, cervix closed 5 p.m. Pains as they were, os one finger dilated, head just tipped 6.45 p.m. Pituitrin 1 in 2,500 + quinine 4 gr (0.26 g) started, B.P. 150/110 mm Hg 7.45 p.m. Patient vomited profusely, weak contractions every five minutes head descending, os almost two fingers dilated 10 p.m. Continuous backache, contractions as before head advancing, os three fingers dilated, pethidine 100 mg given 11.15 p.m. Drip discontinued one bottle given, morphine 1/4 gr hyoscine 1/100 gr given, slept well most of night Jan 11—12 noon Vague uterine contractions, slight backache, B.P. 150/110 mm Hg, os three fingers dilated 12.15 p.m. Pituitrin 1 in 2,500 + quinine 2 gr drip restarted 2.15 p.m. Weak contractions every five minutes, head in mid-cavity, os three fingers dilated, B.P. 150/90 mm Hg 3.30 p.m. Second bottle begun, pains every ten minutes, B.P. 170/110

mm Hg, os three to four fingers dilated head in same position 5 30 p.m. Strong contractions every five minutes, B.P. 140/90 mm Hg, os 3/4 dilated, pethidine 100 mg given 8 30 p.m. Strong contractions every five minutes, rim of cervix only palpated anteriorly, pethidine 100 mg given 9 30 p.m. Third bottle begun, B.P. 140/90 mm Hg, general condition good Jan 12 — 6 a.m. Still small rim of cervix anteriorly pethidine 100 mg given, slept well 11 30 a.m. Second stage begun 2 12 p.m. Precept delivery of living female child, 9 lb (4.08 kg)

Case 9 Uterine Inertia—M.F., aged 20, 1 gravida, 41 weeks 15 1947—5 a.m. Pains started 6 a.m. Admitted to pituitary 9 40 a.m. Pains irregular, membranes intact, head aging, os one finger dilated 4 30 p.m. Weak pains every 20 minutes, membranes intact, no progress 11 30 p.m. Pot brom 1 chloral hydrate 30 gr Sept 16—10 a.m. Pains stronger every six minutes, head engaged, os one finger dilated 2 p.m. Pains fairly strong, no progress 5 p.m. No progress, pains weak, pituitrin + quinine 2 gr + pethidine 150 mg drip 5 55 p.m. Pains stronger—every 5 minutes 7 30 p.m. Os two fingers dilated 4 55 p.m. Pains strong, os three fingers dilated, pethidine 100 mg 4 55 p.m. Second bottle started 10 33 p.m. Spontaneous delivery of a living male child, 7 lb 11 oz (3.49 kg)

### Discussion

The pituitrin drip may cause no uterine contractions if the woman is not in labour, and on the other hand may cause strong uterine contractions within five minutes, even within one minute, of its commencement. We have come to the conclusion that a 1 in 2,500 solution is too strong and that the optimum dilution possibly lies between 1 in 5,000 and 1 in 10,000 of the post-pituitary extract. Kamm *et al* (1928) stated that they had prepared post-pituitary extracts having an oxytocic activity 150 times greater than that of the standard powder, and later writers have made similar claims (Stehle and Fraser, 1935, Du Vigneaud *et al*, 1933). None of these authors claims to have isolated the oxytocic principle in pure form, so that it is reasonable to assume that the post-pituitary oxytocic principle possesses an oxytocic activity at least 150 times greater than that of the international standard powder. Let it therefore be assumed (a) that the post-pituitary gland elaborates an oxytocic principle at least 150 times more potent than that of the standard powder, (b) that the average pregnant woman possesses three litres of blood plasma, (c) that none of the oxytocic activity becomes adsorbed to the red blood corpuscles, and (d) that labour pains do not start until after the drip has been running for five minutes, during which time  $\frac{200}{17}$ , or 12 ml, of the drip has entered the blood stream.

It would then follow that a concentration of the oxytocic principle in the blood plasma not exceeding  $\frac{10,000}{12} \times 3,000 \times 150 = 1.375 \times 10^6$  may suffice to initiate or to stimulate uterine pains.

In those cases in which spontaneous rupture of the membranes occurs before the onset of labour we consider it desirable to add 2 gr of quinine hydrochloride to each bottle of glucose-saline solution in addition to the post-pituitary extract. If uterine contractions do not occur it is obviously desirable to take down the drip after two bottles have been given and to restart it on the following day. In such cases it often happens that strong pains occur immediately the drip is recommenced.

The pituitrin drip does not cause a woman suffering from uterine inertia to have very strong pains, but it does in most every case increase both the frequency and the intensity of the pains. An elderly primigravida may be in labour for three days and longer without any advance of presenting part and without any dilatation of the cervical os. The pains, although ineffective, suffice to exhaust her. Morphine and other drugs potent enough to afford the woman adequate rest tend to put her "out of our". The pituitrin drip is invaluable in such cases and

makes possible the use of morphine and pethidine, for the drip can be continued while the patient is adequately narcotized. If we had to choose between the narcotic drugs and the pituitrin drip we should unhesitatingly choose the former, but we believe the drip to be a very valuable aid in the treatment of these peculiarly difficult cases.

The uterus apparently relaxes completely between the pains stimulated by the pituitrin drip. Slight irregularities in the foetal heart were noted occasionally, particularly when the 1 in 2,500 pituitrin drip was used. In such cases the drip was slowed. No permanent adverse effects on the foetus were observed. We consider it perfectly safe to use the pituitrin drip in cases of contracted pelvis when the head is not engaged, in cases of hypertension, and in cases of placenta praevia. It will be seen that Case 2 was previously delivered by a classical caesarean section. We no longer consider it safe to allow such patients to undergo trial labour, and for this reason we regard it as unsafe to administer the pituitrin drip to such cases. We know of no other contraindication to the use of the pituitrin drip provided it is thought desirable to stimulate the uterine pains.

Schockaert and Lambillon (1937) showed that the intravenous injection of "tonephin" (a post-pituitary pressor preparation) caused a higher and more prolonged rise in the blood pressure of patients suffering from "pre-eclamptic toxæmia" than in normal pregnant women, and these findings have been confirmed by de Valera and Kellar (1938) and by Browne (1944). The pituitrin drip causes no elevation of the blood pressure in normal patients, but a rise is sometimes detected in patients suffering from hypertension (see Case 9). The elevation is usually temporary, and strictly similar rises have been noted when a 1 in 10,000 dilution of "pitocin" \* was used. We propose in a subsequent paper to discuss this matter more fully, to record the antidiuretic effects, and to reproduce kymographic tracings of the uterine contractions caused by the pituitrin drip.

### Summary

A dilution of the oxytocic principle of post-pituitary extract in the blood plasma of an order not exceeding  $1.375 \times 10^6$  is capable both of initiating and of augmenting labour pains in man. This dilution is comparable to that of the antidiuretic principle which suffices to inhibit water diuresis. This evidence makes it increasingly difficult to believe that the post-pituitary gland is normally concerned either with regulating or with elevating the blood pressure.

The use of the pituitrin-quinine drip is of great value in those cases in which the woman fails to go into labour subsequent to the rupture of the membranes, whether spontaneously or as the result of surgical intervention.

The pituitrin drip increases both the frequency and the intensity of the uterine pains in cases of uterine inertia and makes possible the adequate use of sedative drugs in the conduct of the labour.

The pituitrin drip may be used in all cases in which it is considered desirable and safe to stimulate the uterine pains, and it is immaterial whether the woman is a primigravida or a multigravida, whether or not she suffers from hypertension, or whether the head is above the brim.

It is not impossible that it will be found advantageous to apply the pituitrin drip to a wider range of cases. It is also possible that it will find a place in the third stage of labour, particularly in those cases of severe post-partum haemorrhage in which the placenta is retained. The pituitrin would of course be added to the transfused blood.

We have in the majority of cases used pituitrin, but pitocin would appear to be equally efficacious, and it would perhaps be more logical to use the latter preparation, particularly in those cases which manifest hypertension.

\*A commercial preparation of the oxytocic principle of the post-pituitary gland prepared by Messrs Parke and Sons.

## SUBTOTAL COLECTOMY AND COLECTOMY IN ULCERATIVE COLITIS

BY

Sir HUGH DEVINE, MS (Melb), Hon FRCS

AND

JOHN DEVINE, MS (Melb), FRCS

The treatment of ulcerative colitis in this country has always been regarded as medical. Like most Australian surgeons, we have had little experience of the surgical treatment of this condition because patients suffering from ulcerative colitis are only referred for surgical treatment as a last resource. In three metropolitan hospitals over a ten-year period, the Royal Melbourne (in this hospital the ten-year period did not include the last two years), the Alfred, and St Vincent's, 341 patients suffering from ulcerative colitis were admitted. Of these, 87 died and 23 were treated surgically (in one hospital 3 cases, in another 5 and in a third 15). There were 6 cases of appendicostomy, 6 of ileostomy, 5 of colostomy, 1 of ileosigmoidostomy, 1 of ileocolostomy, and 1 of colectomy. Of the 6 patients subjected to enterostomy 5 died.\*

From these figures we may infer that in Victoria the incidence of ulcerative colitis is material, that its treatment has been mostly medical and has not been very successful, and that what little surgical treatment has been practised has not been of much value. This paper is founded on a relatively small series of cases, but they were desperate ones, and the later cases reflect team work by the authors—a necessary method of work in this critical surgery which demands painstaking and scientific preparation, often synchronous operating, small bedside operations, skilful post-operative methods, and constant surgical attention. Our interest in the radical surgical treatment of this condi-

tion was awakened by a particularly bad case which came under our notice (H B D) in 1941.

**Case 1**—A woman aged 34, who had been ill for six months with obscure abdominal symptoms, a progressive secondary anaemia, and some disturbance of her bowel function, became acutely ill with severe abdominal pain. She was operated on in the belief that she had an acute appendicitis, the appendix appeared acutely inflamed. About a week after the operation she began to have frequent and painful bowel actions and to pass large quantities of blood with some pus. It was apparent that she had a fulminating ulcerative colitis. Sigmoidoscopy confirmed this diagnosis and showed that the rectum was also badly affected. Notwithstanding many blood transfusions and every kind of treatment she steadily got worse until she was emaciated, cachectic, exhausted, and almost moribund.

FIG 1—A=divided ileum, B=divided sigmoid, C=some mobilization of rectum, D=some prolapse of peritoneum of anterior abdominal wall around the sigmoid remnant so that when the bowel-ends are being closed the size of the sigmoid remnant can be reduced by amputation.

Conservative surgical measures such as appendicostomy or enterostomy could offer little hope of cure and she was too weak to stand a colectomy. We decided therefore on a 'piecemeal' surgical approach, each successive step in treatment being designed not only to bring about improvement but also to be a stage in the removal of the colon. (a) An enterostomy was so planned that it was a step in the formation of an ileorectostomy (Figs 1 and 2).

FIG 2—A=distal end of the ileum, B=distal sigmoid, C and D show the ileosigmoid anastomosis made up of proximal end of ileum and distal end of sigmoid, E=rectum.

(b) About five weeks later the ileum was connected to the rectum by the use of a special spur-clamp (Fig 3) and the open ends of the bowel taking part in the anastomosis were closed under local anaesthesia (Figs 4 and 5). (c) The colon, now isolated, with both ends open forming two mucous fistulae was completely out of action and was treated by routine chemotherapy over a period of months until the patient ceased to improve. Since she had no discharging enterostomy and was comparatively comfortable the length of

FIG 3

Hg, os three to four fingers dilated, head in same position 30 p.m. Strong contractions every five minutes, B.P. 140/90  
 Hg, os 3/4 dilated, pethidine 100 mg given 8.30 p.m.  
 Strong contractions every five minutes, rim of cervix only palpated anteriorly, pethidine 100 mg given 9.30 p.m. Third bottle begun, B.P. 140/90 mm Hg, general condition good Jan 12 — 6 a.m. Still small rim of cervix anteriorly, pethidine 100 mg given, slept well 11.30 a.m. Second stage begun 2.12 p.m. Forceps delivery of living female child, 9 lb (4.08 kg)

Case 9 Uterine Inertia—M.F., aged 20, 1 gravida, 41 weeks Sept 15, 1947—5 a.m. Pains started 6 a.m. Admitted to hospital 9.40 a.m. Pains irregular, membranes intact, head engaging, os one finger dilated 4.30 p.m. Weak pains every 20 minutes, membranes intact, no progress 11.30 p.m. Pot brom and chloral hydrate aa 30 gr Sept 16—10 a.m. Pains stronger—every six minutes, head engaged, os one finger dilated 2 p.m. Pains fairly strong, no progress 5 p.m. No progress, pains weak, pituitrin + quinine 2 gr + pethidine 150 mg drip 5.55 p.m. Pains stronger—every 5 minutes 7.30 p.m. Os two fingers dilated 8.45 p.m. Pains strong, os three fingers dilated, pethidine 100 mg 8.55 p.m. Second bottle started 10.33 p.m. Spontaneous delivery of a living male child, 7 lb 11 oz (3.49 kg)

### Discussion

The pituitrin drip may cause no uterine contractions if the woman is not in labour, and on the other hand may cause strong uterine contractions within five minutes, even within one minute, of its commencement. We have come to the conclusion that a 1 in 2,500 solution is too strong, and that the optimum dilution possibly lies between 1 in 5,000 and 1 in 10,000 of the post-pituitary extract. Kamm *et al* (1928) stated that they had prepared post-pituitary extracts having an oxytocic activity 150 times greater than that of the standard powder, and later writers have made similar claims (Stehle and Fraser, 1935, Du Vigneaud *et al*, 1933). None of these authors claims to have isolated the oxytocic principle in pure form, so that it is reasonable to assume that the post-pituitary oxytocic principle possesses an oxytocic activity at least 150 times greater than that of the international standard powder. Let it therefore be assumed (a) that the post-pituitary gland elaborates an oxytocic principle at least 150 times more potent than that of the standard powder, (b) that the average pregnant woman possesses three litres of blood plasma, (c) that none of the oxytocic activity becomes adsorbed to the red blood corpuscles, and (d) that labour pains do not start until after the drip has been running for five minutes, during which time  $\frac{200}{17}$ , or 12 ml, of the drip has entered the blood stream it would then follow that a concentration of the oxytocic principle in the blood plasma not exceeding  $1 \text{ in } \frac{10,000}{12} \times 3,000 \times 150 = 1 \text{ in } 375 \times 10^6$  may suffice to initiate or to stimulate uterine pains.

In those cases in which spontaneous rupture of the membranes occurs before the onset of labour we consider it desirable to add 2 gr of quinine hydrochloride to each bottle of glucose-saline solution in addition to the post-pituitary extract. If uterine contractions do not occur it is probably desirable to take down the drip after two bottles have been given and to restart it on the following day. In such cases it often happens that strong pains occur immediately the drip is recommenced.

The pituitrin drip does not cause a woman suffering from uterine inertia to have very strong pains, but it does in almost every case increase both the frequency and the intensity of the pains. An elderly primigravida may be in labour for three days and longer without any advance of the presenting part and without any dilatation of the external os. The pains, although ineffective, suffice to exhaust her. Morphine and other drugs potent enough to afford the woman adequate rest tend to put her "out of labour." The pituitrin drip is invaluable in such cases and

makes possible the use of morphine and pethidine, for the drip can be continued while the patient is adequately narcotized. If we had to choose between the narcotic drugs and the pituitrin drip we should unhesitatingly choose the former, but we believe the drip to be a very valuable aid in the treatment of these peculiarly difficult cases.

The uterus apparently relaxes completely between the pains stimulated by the pituitrin drip. Slight irregularities in the foetal heart were noted occasionally, particularly when the 1 in 2,500 pituitrin drip was used. In such cases the drip was slowed. No permanent adverse effects on the foetus were observed. We consider it perfectly safe to use the pituitrin drip in cases of contracted pelvis when the head is not engaged, in cases of hypertension, and in cases of placenta praevia. It will be seen that Case 2 was previously delivered by a classical caesarean section. We no longer consider it safe to allow such patients to undergo trial labour, and for this reason we regard it as unsafe to administer the pituitrin drip to such cases. We know of no other contraindication to the use of the pituitrin drip provided it is thought desirable to stimulate the uterine pains.

Schockaert and Lambillon (1937) showed that the intravenous injection of "toncphin" (a post-pituitary pressor preparation) caused a higher and more prolonged rise in the blood pressure of patients suffering from "pre-eclamptic toxæmia" than in normal pregnant women, and these findings have been confirmed by de Valera and Kellar (1938) and by Brown (1944). The pituitrin drip causes no elevation of the blood pressure in normal patients, but a rise is sometimes detected in patients suffering from hypertension (see Case 9). The elevation is usually temporary, and strictly similar rises have been noted when a 1 in 10,000 dilution of "pitocin" \* was used. We propose in a subsequent paper to discuss this matter more fully, to record the antidiuretic effects, and to reproduce kymographic tracings of the uterine contractions caused by the pituitrin drip.

### Summary

A dilution of the oxytocic principle of post-pituitary extract in the blood plasma of an order not exceeding  $1 \text{ in } 375 \times 10^6$  is capable both of initiating and of augmenting labour pains in man. This dilution is comparable to that of the antidiuretic principle which suffices to inhibit water diuresis. This evidence makes it increasingly difficult to believe that the post-pituitary gland is normally concerned either with regulating or with elevating the blood pressure.

The use of the pituitrin quinine drip is of great value in those cases in which the woman fails to go into labour subsequent to the rupture of the membranes, whether spontaneously or as the result of surgical intervention.

The pituitrin drip increases both the frequency and the intensity of the uterine pains in cases of uterine inertia and makes possible the adequate use of sedative drugs in the conduct of the labour.

The pituitrin drip may be used in all cases in which it is considered desirable and safe to stimulate the uterine pains and it is immaterial whether the woman is a primigravida or a multigravida, whether or not she suffers from hypertension, or whether the head is above the brim.

It is not impossible that it will be found advantageous to apply the pituitrin drip to a wider range of cases. It is also possible that it will find a place in the third stage of labour, particularly in those cases of severe post partum haemorrhage in which the placenta is retained. The pituitrin would of course be added to the transfused blood.

We have in the majority of cases used pituitrin, but pitocin would appear to be equally efficacious, and it would perhaps be more logical to use the latter preparation, particularly in those cases which manifest hypertension.

## SUBTOTAL COLECTOMY AND COLECTOMY IN ULCERATIVE COLITIS

I.

Sir HUGH DEVING, MS (Melb.), Hon F.R.C.S.

AND

JOHN DEVING, MS (Melb.), F.R.C.S.

The treatment of ulcerative colitis in this country has always been regarded as medical. Like most Australian surgeons, we have had little experience of the surgical treatment of this condition because patients suffering from ulcerative colitis are only referred for surgical treatment as a last resource. In three metropolitan hospitals over a ten year period, the Royal Melbourne (in this hospital the ten year period did not include the last two years), the Alfred, and St Vincent's, 341 patients suffering from ulcerative colitis were admitted. Of these, 87 died and 23 were treated surgically (in one hospital 3 cases, in another 5 and in a third 15). There were 6 cases of appendicectomy, 6 of ileostomy, 5 of colectomy, 1 of ileosigmoidostomy, 1 of ileocolostomy, and 1 of colectomy. Of the 6 patients subjected to enterostomy 5 died.\*

From these figures we may infer that in Victoria the incidence of ulcerative colitis is material, that its treatment has been mostly medical and has not been very successful, and that what little surgical treatment has been practised has not been of much value. This paper is founded on a relatively small series of cases, but they were desperate ones, and the later cases reflect team work by the authors—a necessary method of work in this critical surgery which demands painstaking and scientific preparation, often synchronous operating, small bedside operations skilful post-operative methods, and constant surgical attention. Our interest in the radical surgical treatment of this condi-

tion was awakened by a particularly bad case which came under our notice (H.B.D.) in 1941.

**Case 1**—A woman aged 34, who had been ill for six months with obscure abdominal symptoms, a progressive secondary anaemia, and some disturbance of her bowel function, became acutely ill with severe abdominal pain. She was operated on in the belief that she had an acute appendicitis, the appendix appeared acutely inflamed. About a week after the operation she began to have frequent and painful bowel actions and to pass large quantities of blood with some pus. It was apparent that she had a fulminating ulcerative colitis. Sigmoidoscopy confirmed this diagnosis, and showed that the rectum was also badly affected. Notwithstanding many blood transfusions and every kind of treatment she steadily got worse until she was emaciated, cachectic, exhausted, and almost moribund.

Conservative surgical measures such as appendicectomy or enterostomy could offer little hope of cure and she was toned up to stand a colectomy. We decided therefore on a piece-meal surgical approach, each successive step in treatment being designed not only to bring about improvement but also to be a step in the removal of the colon. (a) An enterostomy was so planned that it was a step in the formation of an ileorectostomy (Figs 1 and 2).

(b) About five weeks later the ileum was connected to the rectum by the use of a special 'pur-champ' (Fig. 3) and the open ends of the bowel taking part in the anastomosis were closed under local anaesthesia (Figs 4 and 5). (c) The colon, now isolated, with both ends open forming two mucous fistulae was completely out of action and was treated by routine chemotherapy over a period of months.

FIG 3

\*For the information we acknowledge our indebtedness to Dr George Gunther, of the Royal Melbourne Hospital, Dr Smibert, of the Alfred Hospital, and Dr Carl DeGruchy, of St Vincent's Hospital, who kindly collected it, and to the respective hospitals for their generous permission to publish the figures.

until the patient ceased to improve. Since she had no discharge from enterostomy and was comparatively comfortable, the length of this period was immaterial and we could wait almost any time (in this case eight months) till we felt that she was thoroughly

fit for the last stage—namely, (d) a colectomy (or near-colectomy), which in this instance was done in one stage after a period of painstaking preparation

### Main Principles

Certain main principles should govern this surgical procedure (1) A very careful preparation to correct hypoproteinaemia and anaemia (2) A graduated method so that when the colon is removed there is no sudden dislocation of function (3) No stage should be undertaken until the

FIG 4—A=clamp made of hard aluminium alloy, in position to crush the spur, B=ileum, C=sigmoid, D=rectum

FIG 5—A=openings of excluded bowel, B=ileum C=closed ends of the ileum, D=lower segment of the sigmoid

brittle tissue. The rectum is mobilized upwards and a small segment of the lowest part of the sigmoid is preserved so that this spur-clamp (Fig 3) can be used

In Case 1 when the resected colon was examined it was found to be 2 ft 9 in (84 cm) long and uniformly affected with an advanced stage of acute ulcerative colitis. In the ileocaecal region there was a group of very large inflamed glands, nowhere else were the glands enlarged to any extent. The patient began to improve soon after the ileum was connected to the rectum. For eight months while her isolated colon was washed out with sulphonamide solutions her general condition improved steadily and she became much heavier and began to look well. There was, however, little improvement in the colon, an examination showed little or no improvement in the condition of the mucous membrane and pus poured from the mucous fistulae in large quantities. Then her general condition ceased to improve and this determined the time for her colectomy. This operation caused her little disturbance. The isolated colon was much retracted and much smaller than normal and was thus comparatively easy to remove. Four months after her colectomy she began to improve rapidly. The badly diseased rectum began gradually to clear up. A few tiny ulcers formed in the ileum, but these

soon disappeared. This patient is now, six years later, a red-faced, healthy-looking person, she is 4 stone (25.4 kg) heavier and has no signs of active disease in her rectum. Her bowels open six to eight times a day and twice at night (This is unusually frequent, as we shall see from later cases). She has, however, a group of inflammatory glands which can be felt in the left iliac fossa and which on x-ray seem to be well away from the rectal anastomosis.

through the

Case 2—A man of 54 had suffered from a severe ulcerative colitis for three years. He had hourly motions, had lost a lot of weight, had become cachectic, was unable to work and was very sick indeed. X-ray and sigmoidoscopic examination showed that extensive and irreparable structural changes had taken place in the bowel. A modified enterostomy as described in Case 1 (Fig 1), the first stage of the subtotal colectomy, was done (HBD). His general condition began to improve but the repair of his abdominal wound was weak and a superficial mild but spreading ulceration formed around the enterostomy. Then about two months after his ileum had been connected to his rectum strangulation of a loop of bowel occurred under a band like section of ileum which was attached to the anterior abdominal wall. He recovered from the operation, but died some months later from bronchopneumonia.

This case was a failure. He never derived much benefit from his enterostomy, never improved enough to enable us to proceed with the stages of his colectomy, and never had a healthy-looking abdominal wound. Deficient tissue vitality as shown by lack of repair in his enterostomy wound and by his terminal bronchopneumonia was probably the direct result of an intense toxemia and of protein loss from the large ulcerating surface. Careful pre-operative measures to counteract his hypoproteinaemia had never been properly carried out.

Case 3—This patient was in just as desperate a condition as Case 1. He had been sick for four years. He had ten or more motions a day and several at night with copious blood and pus. He weighed 7 stone (44.5 kg) and looked like a person in the last stages of tuberculosis.

This patient was operated on (HBD) in much the same way as Case 1. When examined after removal the colon was over 3 ft (91 cm) long and showed a late stage of the disease involving the whole colon. After the colectomy there was a dramatic improvement and in 12 months the patient was able to do light work.

Two years after the colectomy he developed an acute intestinal obstruction. An operation (JBD) relieved this. Now three years after his operation he appears to be quite well. He has been back at full work for one year and is 5 stone (31.8 kg) heavier. The number of his motions has gradually diminished till now he has two in the day—one in the morning and one before going to bed. He says 'The motions are not formed, but they are not liquid they are softish. The tip of a finger introduced into the rectum enters the ileum. Sigmoidoscopy shows that the disease in his rectum has completely cleared up.'

Four years after the colectomy he developed an acute intestinal obstruction. An operation (JBD) relieved this. Now three years after his operation he appears to be quite well. He has been back at full work for one year and is 5 stone (31.8 kg) heavier. The number of his motions has gradually diminished till now he has two in the day—one in the morning and one before going to bed. He says 'The motions are not formed, but they are not liquid they are softish. The tip of a finger introduced into the rectum enters the ileum. Sigmoidoscopy shows that the disease in his rectum has completely cleared up.'

### Four More Cases

Case 4—A woman of 43 was very wasted, acutely ill (pulse 130), and looked as if she would only live a month. For 18 months she had had all the symptoms and signs of a very severe ulcerative colitis in which the rectum was also involved. She had weeks of intensive preparation before any operation could be considered. With a great struggle she got through her first stage operation carried out as in Case 1. She was so sick that the periods between the operative steps had to be long. Her tissues had very poor vitality, a slab of tissue in the abdominal wall lying over the anastomosis with the rectum, came away as a large slough. After each operation she improved, until finally we were able to remove her colon. The colon was white and opaque looking, greatly thickened, oedematous and uniformly involved. The appendix was in two parts, the division lying in the midst of evidences of a past abscess.

Two years later this patient was comparatively well. She had gained much weight and was doing her own housework.

The rectal condition was almost normal. She had six stools in 24 hours—four during the day two during the night. A sinus still remained in the lower part of the abdominal scar where the slough had occurred.

**Case 5**—A young man of 22 had had a very severe ulcerative colitis of two years' duration; he had spent six months in hospital. He received the usual careful pre-operative preparation with a view to correcting haemoglobin and protein deficiency. Immediately after the first stage of his surgical treatment—that is after the modified enterostomy (HBD)—he became painlessly distended and notwithstanding Miller-Abbott therapy, jejunostomy, and every possible measure including abdominal exploration (JBD) he died of what we regarded as a paralytic ileus.

**Case 6**—This patient reached a stage of almost complete cure and then died from an adventitious cause. He was 60 and had suffered from a bad ulcerative colitis for two years. The colon was removed in the way already described (HBD). Following the operation his condition improved and reports two years later indicated that he was comparatively well. About this time a report reached us that he had died suddenly up country from an acute intestinal obstruction (no operation).

**Case 7**—This woman of 37 had had an ulcerative colitis for 20 years and had been under my care (HBD) for that time. In its early stages the colitis had been very severe for three years and she had been practically bedridden. In an effort to help her a valvular appendicostomy was made and into this we inserted an indwelling catheter (HBD) which never leaked. Through this she gave herself a daily wash out and after a time she became well enough to earn her living.

Years later there was an exacerbation of the disease and finally a stricture formed in the lower 3 in (7.5 cm) of her sigmoid. This became so narrow that surgical treatment was imperative. Accordingly her colon was removed by the 'sliding scale' method already described (HBD and JBD). Since the stricture was in the lowest 3 in. of sigmoid it could be included in the spur. Thus with the distal cut end of the sigmoid opening on to the abdominal wall, the stricture could be so dilated as to permit the intro-

FIG 6

duction of the enterotome, so that when the spur was crushed it was divided (Fig 6) and the stricture became part of the anastomosis.

Two and a half years after the operation this patient has greatly improved. Her colour has completely changed and she looks healthy; she has increased greatly in weight, is able to do full work and to defecate comfortably. The number of her motions has become less and less until now they are four a day and none at night. Sigmoidoscopy shows that the disease in the rectum has almost cleared up, the signs of inflammation are gone and there is much scarring, but there still remains one small ulcer.

#### Possibilities of Surgery

The next case was a good example of what surgery can do for ulcerative colitis. It concerned a distressing and pitiable case of four years' duration in a 19-year-old girl. In the early stages of her illness a properly constructed

enterostomy had been done. For twelve months after this she continued to improve, but then began to relapse rather badly and soon became very ill indeed. Although her condition was desperate we felt justified in facing up to a colectomy because of her youth. The most favourable time for operation, when the patient had derived the greatest benefit from the enterostomy, had long passed. Her general condition was very bad. Her tissues had almost lost the power of repair, a small wound in the abdominal wall had not healed in nine months. There were fistulae from the rectum into the vagina, and there was a stricture in the rectosigmoid region. The disease in the rectum was so advanced that it was obvious that this organ was irrecoverable.

**Case 8**—Special care was taken in her pre-operative preparation. Blood and serum to correct her anaemia and hypoproteinaemia were given well before the operation so as to get their full effect. At operation (HBD and JBD) it was seen that while the distal colon was severely affected the proximal colon showed no evidence of the disease. The disease was so advanced as to preclude the possibility of the colon ever functioning normally: there was a perforation in the sigmoid, and it was obvious that the rectum would eventually have to be removed.

In this case we thought it wise to take advantage of the absence of disease in the proximal colon to preserve the ascending colon as it would provide a more controllable artificial anus than would the terminal ileum (the wisdom of this was subsequently proved). The colon was resected from the hepatic flexure to a point about 3 in (7.5 cm) above the recto-sigmoid junction. The cut end of the distal segment of the sigmoid was implanted in the lower end of the wound, the peritoneum of the anterior abdominal wall being stripped and well prolapsed into the abdominal cavity round the stump so as to leave as small a segment of sigmoid as possible. A small carefully constructed artificial anus which could be controlled was made at the hepatic flexure. At a second operation the enterostomy was closed. The wound however, showed little tendency to heal.

For about nine months her general health continued to improve, after which she was again so ill that it looked as if she would surely die. We were freed with a most adverse set of circumstances, a profound deterioration of general health and of all her bodily functions, wounds from the previous operation which had not yet completely healed and spreading areas of cellulitis in various parts of her body. Nevertheless because she was only 19 we decided to operate.

She was first given several blood transfusions. Later, under nitrous oxide anaesthesia (Dr Travers) with two sets of instruments and two nursing teams—one for the abdominal surgeon (HBD) and one for the perineal surgeon (JBD)—the rectum was removed in just over the half-hour with astonishingly little disturbance to the patient. Penicillin was used as dressing in the large infected cavity left after the rectum was removed.

Her general condition began to improve very slowly, but for many months the rectal cavity showed no sign of healing. Finally a stage was reached when it began to heal very slowly; it was well over 12 months before it had closed.

Now, over three years later, she seems to have completely recovered. She looks perfectly healthy, has gained stones in weight, is able to ride and to drive a car, and carries out nursing duties for her father who is a doctor. What is most gratifying is that thanks perhaps to the fact that she has her ileocaecal valve, or that a small part of her colon was left to make the artificial anus, she has a practical control of her bowel. She gives herself a wash-out through the colostomy once a week and until her next wash out her abdominal wall is never soiled. This is unusual but is cited to show the value of preserving the proximal part of the colon. That a patient as ill as this girl was could survive removal of most of her colon and the whole of her rectum and could get so well that she could lead a normal life has

made us revise our surgical philosophy in so far as it applies to the treatment of desperate cases of ulcerative colitis.

In this case we see some traits of the worst form of the disease—the intractable type of ulcerative colitis, the specific deficiency in tissue repair, the general dissemination of the infection as seen by the areas of cellulitis, and the greater incidence of the disease in the distal colon and particularly in the rectum. In it, too, we see the temporary value of enterostomy, the powers of recovery of youth in a desperate case of ulcerative colitis, the importance of taking advantage of an unaffected caecum and ascending colon, and the fact that in this case after all that was done to her she is able to live practically a normal life.

### Partial Colectomy

Another case showed how a partial colectomy may help in some patients. A man of 57 had had an ulcerative colitis for 20 years. He was cachectic, emaciated, and dehydrated. He had been having motions, mostly of pus and blood, 12 or more times a day and three or four at night. About 18 months before coming into hospital he had begun to have attacks which were diagnosed as due to chronic intestinal obstruction. A 3-in (7.5 cm) stricture in the middle of the transverse colon and another but shorter one in the rectosigmoid region could be seen in a radiograph. A long, hard, nodular tumour, which was undoubtedly malignant, could be felt in the region of the transverse colon corresponding to the site of the stricture.

*Case 9*—At operation (HBD) a long sausage shaped malignant growth was found occupying the greater part of the transverse colon. The walls of his chronically inflamed colon were about 1/4 in (6 mm) thick, rigid, and friable. To suture such a colon would be impossible. Here it was obvious that the only way to effect an anastomosis was to make a spur and use a bevelled edged enterotome so as to crush by graduated pressure rather than cut through the rigid and friable tissue. The hepatic flexure and the adjoining part of the ascending colon, the transverse colon, the splenic flexure, the descending colon, and the upper half of the sigmoid were stripped from the posterior abdominal wall as one large segment. The limbs consisting of mobilized ascending colon and hepatic flexure and mobilized descending colon and sigmoid were sutured together to form a spur. The tumour-containing segment was then widely amputated. Later the spur was crushed by the gradual application of a bevelled edged enterotome. The patient recovered and for three years enjoyed a comparatively comfortable life.

The lesson to be learnt from this case is that extensive partial colectomy—subtotal colectomy—has a value in the surgical treatment of ulcerative colitis. So much of his diseased colon was removed that the toxic effects of, and the miseries attendant on, the inflamed and ulcerated colon were greatly ameliorated. This patient died three years later following an attempt to remove the rectosigmoid stricture, which appeared also to have become malignant.

### Low Stricture of the Rectum

The next case had a special interest in that it showed how a fairly low stricture of the rectum could be dealt with.

A girl aged 19 had had ulcerative colitis for six years. Sigmoidoscopy showed that the rectum and sigmoid were almost completely denuded of mucosa, there was a foul, frothy, semi-purulent discharge. A radiograph showed absence of haustration, rigidity of the bowel, and loss of the mucosal pattern as far as the splenic flexure. The remaining colon had a normal appearance. The patient looked very sick and had a haemoglobin of 65% on the 14-gramme standard.

*Case 10*—As the disease was confined to the descending colon, sigmoid, and rectum, a transverse "defunctioning" colostomy was done in August, 1946 (JBD), under gas and

ether anaesthesia. The idea was that as the patient was a young girl the question of resecting the distal part of the colon and making an anastomosis between a long proximal part of the transverse colon and the rectum should be considered if the "defunctioning" colostomy did not bring about healing of the disease. Following this operation, the patient improved and her weight increased by half a stone (3.2 kg).

By March, 1947, she was again having almost continual rectal bleeding and her general health was no longer improving. She now had a stricture 2 in (5 cm) from the anus through which the tip of the examining finger could not be passed. So at the Alfred Hospital under gas, oxygen, and ether anaesthesia a midline lower abdominal incision was made and the rectum was dissected free to within 1/2 in (1.25 cm) of the anus. The ileum was then transected and its acting loop brought down and sutured alongside the rectum as low in the pelvis and as near to the anus as possible. A spur was thus created with ileum going to below the stricture, and the end of the rectosigmoid stump was also implanted in the wound. At the same time the colon was removed from the rectosigmoid junction region as far as the transverse colostomy.

Six days after the operation a crushing clamp was applied as shown in Fig. 6, and the stricture was crushed into the ileum. Thus a free passage of ileal contents into the rectum was assured. At a later date, under thiopentone, the acting loop of the ileum and the rectosigmoid stump opening on to the abdominal wall were closed. The specimen removed was 3 1/2 ft (105 cm) long, and showed considerable fibrosis and much loss of mucosa. Following this operation the patient had put on weight and had become engaged to be married. She was having two bowel motions in the 24 hours.

Sigmoidoscopy before she left hospital revealed improvement of the disease in the rectal pouch, which had previously been markedly involved. There was a wide opening between the ileum and rectum. Three or four months later, by which time she was in every way a normal girl, sigmoidoscopy failed to reveal any disease in the rectum. It was now thought advisable to remove the isolated segment of ileum and caecum and ascending colon. This was done and she progressed favourably until the tenth day, when she developed a subphrenic abscess. The abscess was drained surgically below the twelfth rib. Drainage ceased in about a fortnight, and the next stage of her progress was uneventful except for the slow healing-over of a fistula from the ileo-rectal anastomosis which was inadvertently opened at the preceding operation.

Our last patient (Case 11), aged 55, was a woman who had suffered from diarrhoea, often having 15 motions in each 24 hours, and loss of weight. She had become very depressed and the disease had reached a late stage. The first stage of the operation (the junction of the ileum to the rectum and closing the ileo-rectal fistula) was carried out. The patient has been sent home where she can live comfortably, having only a slight mucous discharge from the two mucous fistulae. She can do her own work, so there is no hardship in her remaining any length of time, so long as she continues to improve, before the final stage, a colectomy, is carried out. This case is included to show the comfortable life that patients can lead while waiting for their colectomy, and also because we feel that it is in the first-stage operation that the danger lies.

### Future Policy

Although our series is small it includes such bad cases and good results that we feel we are entitled to build from it a surgical philosophy for our future treatment of ulcerative colitis. We believe, first, that a case of established ulcerative colitis should come to a surgical consultation early in its course to consider the question of early operation from the following viewpoints:

(a) Can the surgeon help the physician? He may be able to do so by making a non-leaking valvular appendicostomy (in Case 7 such an appendicostomy functioned for about 18 years without leaking).

(b) There is some justification for the removal of the appendix, since it is not above suspicion as the point of entry of the infective element in the colitis.

(c) To find out early in the course of the disease whether the ascending colon is free from the disease, because in this case the prognosis is much brighter and early operation is justifiable.

(d) To ascertain the type and severity of the ulcerative colitis with a view to planning its treatment. Is it a case which medical treatment will not cure? I think this judgment can be made.

Secondly, we should advise in treatment more attention to tissue resistance and tissue repair. They probably play a larger part in this infective disease than does the virulence of the organism.

Thirdly, we should regard ulcerative colitis in much the same way as we do gastric ulcer, that is, when ulceration and loss of substance of the mucosa have taken place and the physician is making no headway with his treatment we should advise operation with a view to removing the colon, and advise operation early.

We believe that the reward of early colectomy or subtotal colectomy is a low immediate mortality and a very fair chance that the rectum will recover when the colon is removed. We feel it is not wise to wait on and on in the hope of medical cure.

#### Summary

Here were 11 advanced and desperate cases of ulcerative colitis for which a policy of careful radical surgery was planned. In general, it represents a rather timid and tedious method of operation but both the immediate and remote results are more than satisfactory. We look forward to the application of the method to much earlier and less debilitated cases—to cases which from our experience we can say will not be cured by medical treatment.

Of the 11 patients two died. One died of an adynamic ileus immediately following the first-stage modified enterostomy, and one three months after the first stage from tissue deficiency and toxæmia. None of the patients died following colectomy or excision of the rectum. Thus, of 11 desperately sick patients six survived subtotal or near-colectomy, one a near colectomy combined with excision of the rectum, one a partial colectomy involving two thirds of the colon, and one the first stage of colectomy.

Six patients seem to be cured—the worst case of all for six years. They have no bowel discomfort and live normal lives. One patient has only two motions a day and none at night. Most of the patients, however, have from four to five motions in 24 hours.

The Minister of Health recently held a valedictory reception for members of the Rushcliffe Nurses and Midwives Salaries Committees and members of the Advisory Council of the Civil Nursing Reserve, which were disbanded on July 5. The two Rushcliffe Committees worked almost continuously for nearly seven years and have reviewed the pay and conditions in every field of nursing. Their reports and recommendations have covered all grades of nurses, both men and women, in all branches of the hospital and public health field, as well as the midwifery service. In 1941, for example a hospital staff nurse received £70-£80 a year, to day as a result of the Rushcliffe recommendations she receives £140-£200 a year. With the coming into operation of the National Health Service there will be entirely new machinery for dealing with salaries and conditions of service. There is to be a series of Whitley Councils covering all those working in the Service, and one of these will be for nurses and midwives. The Minister of Health paid tribute to the great work of Lord Rushcliffe and the members of his Committees and of the CNR Advisory Council. Lord Rushcliffe in reply said that during a long period in public life nothing had given him greater satisfaction than his association with the Nurses and Midwives Salaries Committees. Their recommendations had not been pigeon holed but had shown prompt results.

## DEATH FROM INHIBITION, AND ITS RELATION TO SHOCK

### A CRITICAL SURVEY

BY

A. I. KAYSSI, M.D. Mont., Dipl. Leg. Med. & Psych. Paris

*Director of the Medico-Legal Institute and Professor of Legal Medicine, Medical College and Faculty of Law, Bagdad*

*(From the Department of Forensic Medicine  
Edinburgh University)*

Among medico-legal experts there is apparent a certain confusion in describing the nature of death from inhibition, and often also between the effects of shock and of inhibition. This is especially so when they are dealing with cases which might fall within either category, and regarding which they have to decide in one way or the other and to present a logical and scientific conclusion to the courts. The medico-legal expert cannot afford to use vague expressions and nomenclature. The pathologist, on the other hand, is not usually subjected to such difficulties and can afford to express opinions that are not necessarily binding, he is at liberty to advance hypotheses which are liable to modification or alteration but which can be so altered without serious consequences.

I propose to draw attention to the manner in which various writers on pathology and legal medicine deal with these matters and other related subjects of special medico-legal interest. We find, for example, in certain medico-legal textbooks special attention given to death due to inhibition with almost entire neglect of the subject of shock, while the exact opposite occurs in some of the books on pathology. Both sides may have their own reasons for this selective handling of their own subject. For instance, the medico-legal expert may contend that shock does not interest him greatly because usually it is possible to attribute the cause of death directly to the injuries so obviously and extensively present—severe trauma such as rupture of viscera, extensive burns, or severe haemorrhages. On the other hand the pathologist may contend that death due to inhibition has no material meaning to him so long as he cannot find microscopic or macroscopic evidence of direct pathological processes which he can hold responsible for the death. Thus both parties appear to be relatively satisfied with the present position in regard to both subjects.

Elsewhere in the literature of forensic medicine and trauma we find an obvious confusion between these two subjects, the terms "inhibition" and "shock" being used loosely and inaccurately as if they were interchangeable—a state of things that is perhaps attributable to recent activity in the study of shock and the frequency with which the subject is referred to in medical periodicals. The fact that shock has become extensively written about seems to have had as a consequence the effect of confusing the two syndromes.

Very few among the leading authorities in forensic medicine, pathology, or physiology deal with the difference between the two subjects with sufficient emphasis, and then only to put death due to inhibition under the title of primary shock while speaking of shock as "delayed shock"—an attitude which has served only to increase the confusion.

I shall endeavour to put forward the real facts concerning the nature and mechanism of both syndromes and of the other phenomena, related to quite different causes, which are ordinarily confused with death due to inhibition.

### What is Inhibition, and How Does it Result in Death?

The term was first used after the discovery by the Weber brothers in 1846 that the excitation of the vagus along its course and irritation of its peripheral end after section give rise to a marked slowing of the heart's action, and that when the excitation is strong enough it may lead to the stoppage of the heart in diastole—i.e., to a complete inhibition of its action.

In 1856 Pflüger established the possibility of inhibiting the intestinal movements as a result of excitation of the ends of the splanchnic nerves. A few years later, in 1861, Rosenthal succeeded in inhibiting the respiration by exciting the vagus centrally. Since then many other workers have proved that this inhibitory action is not limited to the excitation of the main nerve trunks, but can be accomplished by reflex action, as happens after the excitation of the superior laryngeal nerve, which leads to the inhibition of respiration and even to sudden death.

Brouardel, of Paris, was the first to use the term "death due to inhibition." His conception of death due to circulatory or respiratory inhibition was accepted for a long period without contradiction, and indeed it became somewhat abused. Thus we find that till the beginning of this century a large proportion of cases of sudden death were attributed to inhibition in medico-legal records. This proportion, however, diminishes more and more with the progress of pathology, which throws light on the real causes of certain doubtful cases of sudden death for which the term "death due to inhibition" was advanced only to cover ignorance of the real causes of death.

In the early days it was common to speak of two kinds of death from inhibition, primary and secondary, the latter term being used to cover asphyxia and cardiac or respiratory syncope, which were due to definite diseases to which the inhibition was regarded as being secondary. The same descriptive terms were later applied to shock.

### What is Meant by "Death from Inhibition"?

Among the cases reported by medico-legal experts are the following:

Two boys, aged 12 and 14 were playing together when one kicked the other in the abdomen. The victim dropped dead instantaneously. The necropsy did not reveal any lesion which would explain the cause of death, nor was there a trace of ecchymosis on the abdominal wall.

A midwife was practising abortion on a young woman in the early months of pregnancy. While endeavouring to introduce a type of cannula into the cervix the patient suddenly complained of difficulty of respiration, relaxed and died. Nothing was found at the necropsy to explain the cause of death, not even traces of ecchymosis on the cervix.

Other reported cases occurred after the introduction by a surgeon of a catheter into the bladder, and after a slight blow on the testicles. In such cases may be found only superficial abrasions or a little discoloration of the skin on the site of the blow, or even no signs at all.

In my fifteen years' experience of medico-legal cases I have encountered, out of more than 2,000 sudden deaths, two cases which I could not explain except by the mechanism of inhibition.

The first was that of a boy aged 16 leaving his house on the river-bank just after lunch, and wearing his swimming suit. He joined a number of companions, jested with them, and then rushed into the river for a swim. After a few minutes he disappeared from their view and could not be found. His parents were informed, search was made, and the body was recovered a few hours later. A necropsy was performed the same day, before putrefaction had taken place. We found him to be healthy, without any sign of injury, either superficial or deep, on the body. His stomach was full of undigested food, and

there was a small amount of unclotted blood in the heart cavities. No pathological signs were detected in his organs macroscopically, and especially no sign of drowning. For the purpose of accuracy we sent specimens of his viscera—heart, kidneys, suprarenals, spleen, pancreas, liver—for microscopical examination. The report stated that nothing was detected except congestive reaction in the above mentioned viscera, and I personally contacted the family to inquire about his previous state of health. They assured me that he did not complain of any weakness or disease, and that he was a good swimmer. The entire circumstances of the accident were substantiated by his friends.

The second case was that of a police student aged 23. While engaged in a game of football he was struck on the abdomen by the ball and dropped dead while uttering the word "Ah!" The accident was witnessed by the other players, especially by two of his own team very near to him at the time. A necropsy was performed speedily, and before putrefaction took place. No sign of violence was observed either superficially or deep in the muscular layers. A small quantity of unclotted blood was found in the heart cavities and a little food of a pasty consistency in his stomach, there was a general congestion of his viscera, but no pathological signs were detectable either macroscopically or microscopically.

Faced with these two cases, my conclusion was definite that death was due to inhibition, this was supported by (1) the absence of any pathological, traumatic, or toxic signs, and (2) the circumstances which surrounded the fatalities. It was a conclusion reached by exclusion of other possible causes.

### Mechanism of "Death from Inhibition"

It is not necessary to enter into details and relate all the theories and hypotheses of the mechanism. A summary will suffice. The principle discovered by the Weber brothers still obtains and is the basis for the explanation of the occurrence of such cases. With regard to the inhibition reflex physiologists are in accord, their view is that it is accomplished through the centres existing in the central nervous system. According to the latest conception the transmission is performed by the liberation at the nerve-ending of small amounts of highly active substances which exert their effects on, and are quickly destroyed in the tissues. The degree of trauma and the type of irritation which can lead to such changes and to the liberation of the substances which act as the medium for the transmission of the inhibitory reflex have not yet been determined.

### The Domain of "Death from Inhibition"

Death from inhibition as it is generally accepted covers all sorts of sudden death occurring within a few seconds or not longer than two minutes, after trauma or peripheral excitation relatively simple and not in itself sufficient to cause death. No pathological changes which would be liable to account for death must be present at the subsequent necropsy.

All medico-legal authorities are satisfied that this kind of death is explicable only on a basis of the "arrest" or "inhibition" theory by excitation of some part of the vagus. Some authors attach special importance to certain parts of the body, such as the laryngeal, epigastric, testicular, cervical, and cardiac regions, when these are subjected to trauma or irritation. Others endeavour to classify the deaths according to whether they are frequent, rare or exceptional in the regions involved, while some suggest that death may take place irrespective of the area concerned.

I am of the opinion that certain regions, as mentioned above, are of particular importance in this matter and also that there must be a special personal sort of constitutional susceptibility which varies from individual to individual. Highly emotional beings, for example, are

considered to be more liable to such accidents. Such would be the case with persons in full digestive activity and during pregnancy too—conditions which are accompanied by definite humoral changes.

Excessive emotion, termed by some authors psychical trauma—following distasteful news or incidents has been advanced as a cause of death from inhibition. Actually I did not find in the literature any such serious consideration, and if they have occurred it appears probable that they are due either to pre-existing heart disease with emotion provoking a sudden hyperemia or a fatal result in such circumstances can be explained easily. Death occurs as a result of failure of function. So we agree with the author possibly due to the fact that of death due to inhibition by pre-existing disease in the person.

So we agree with the explanation of death due to inhibition occurring only the condition of pre-existing disease. It is known that pre-existing heart disease or disease of many other organs may lead to death. In fact, death may be due to a variety of causes, but the most common is due to a pre-existing disease of the heart or lungs. In such cases, the death is due to the failure of function of the organ affected, and not to inhibition by pre-existing disease in the person.

### Shock

Shock is a condition of the body which is characterized by a sudden fall in blood pressure, a rapid pulse, and a state of unconsciousness. It is a condition which is caused by a variety of factors, including trauma, infection, and internal disease. The condition is characterized by a sudden fall in blood pressure, a rapid pulse, and a state of unconsciousness. It is a condition which is caused by a variety of factors, including trauma, infection, and internal disease. The condition is characterized by a sudden fall in blood pressure, a rapid pulse, and a state of unconsciousness. It is a condition which is caused by a variety of factors, including trauma, infection, and internal disease.

Shock is a condition of the body which is characterized by a sudden fall in blood pressure, a rapid pulse, and a state of unconsciousness. The condition is characterized by a sudden fall in blood pressure, a rapid pulse, and a state of unconsciousness. It is a condition which is caused by a variety of factors, including trauma, infection, and internal disease.

### Factor in Death

Factor in death is a condition of the body which is characterized by a sudden fall in blood pressure, a rapid pulse, and a state of unconsciousness. It is a condition which is caused by a variety of factors, including trauma, infection, and internal disease. The condition is characterized by a sudden fall in blood pressure, a rapid pulse, and a state of unconsciousness. It is a condition which is caused by a variety of factors, including trauma, infection, and internal disease.

**Anoxia.** The accumulation of waste product due to deficient oxygenation of all of it itself result in anoxia and dilatation of the minute vessels. Further of the factors operating alone from the other into action constituting a vicious circle. None of these factors depend upon failure of the heart or of the vasomotor mechanism, but directly upon chemical influences acting on the contractile wall of capillaries.

A disparity between the volume of blood and the volume capacity of the circulatory system may result from the factor, under group 1 or group 2. Usually factors of the two groups are acting simultaneously. The delivery of oxygen to the tissue is reduced in proportion to the decreased volume flow of blood. The factor of itself produces anoxia of the tissues and reduce all metabolic processes.

The factor of anoxia is a condition of the body which is characterized by a sudden fall in blood pressure, a rapid pulse, and a state of unconsciousness. It is a condition which is caused by a variety of factors, including trauma, infection, and internal disease. The condition is characterized by a sudden fall in blood pressure, a rapid pulse, and a state of unconsciousness. It is a condition which is caused by a variety of factors, including trauma, infection, and internal disease.

### Primary Shock

Most of the recent writers on shock incline now to divide the subject into primary and secondary as the criteria, but this is a very serious confusion produced to lead writers by inducing them to record primary shock as the cause of death from inhibition. A thorough search for an example of a case of primary shock produced one which may be said to represent what is really meant by primary shock.

A youth of 19, while lying in a shallow trench, was hit by a shell fragment and suffered a compound fracture of the tibia. He did not lose consciousness. There was no appreciable haemorrhage. Two minutes later his chief complaint was thirst. He had no pain. He was extremely restless, throwing the injured leg about with flail-like motions at the fracture. Although sweating profusely, he complained of feeling cold. Respiration was apparently normal. The pulse, at first slow, later became rapid, and remained small and barely palpable. On the basis of findings in similar cases, his systolic pressure was probably below 70 mm. Mentally he was quite alert and talked about his experiences while the limb was splinted without anaesthesia. Apparently this procedure gave him no pain. Later his condition improved and he was able to be moved to a dressing station.

Shock may develop almost instantly at the time of injury, and it is then known as "primary". It may develop slowly after some hours, and it is then known as "secondary" (Macleod). When primary shock occurs incident to severe injuries it may merge imperceptibly into the grave condition of secondary shock (Moon).

From what has been advanced with regard to primary shock it has become obvious that it is related to one of two things: either it is concerned with a rapid onset of a state of shock or it may be a form of abortive shock, its gravity lies in its possible development into the classical form of shock.

### Distinctive Characteristics

Having reviewed the facts relating to death by inhibition and shock, it seems opportune to compare the main elements distinguishing the two syndromes. It should be pointed out that, despite the infrequent occurrence of pure fatal inhibition, which is usually met with only by medico-legal experts of long experience, it constitutes a special entity all its own, differing completely from shock in its circumstances, its causes, its mechanisms, its symptoms, its pathological results, and—what is of great interest to the medico-legal expert—its legal implications.

This entity covers cases in which relatively simple trauma or peripheral irritation results in death, with a lapse of time not exceeding two minutes, by a special mechanism—namely, an inhibition reflex. Experiments have not yet determined all its elements. Its diagnosis is arrived at by the absolute exclusion of any traumatic, pathological, or toxic cause, acute or chronic, which may be found during the necropsy, and by the circumstances surrounding death. This entity must not be confused with syncope, which is inadequate to express its individuality.

Embolism and prophylactic shock have also different mechanisms, and finally "shock" (traumatic shock), as we have seen, whether primary or secondary, is definitely a different syndrome, being essentially a circulatory deficiency which can be obviated in certain cases, as it can be diagnosed easily in time and can be treated, and does not necessarily end in death. It has an obvious pathological criterion.

### Main Distinctive Characteristics Differentiating Shock and Death by Inhibition

	Shock	Death by Inhibition
Nature	Its major factors: anoxia, anoxia, and vascular dilatation	Its essential factor: arrest of the vital organs
Cause	Macrotrauma producing extensive destruction or haemorrhage	Microtrauma producing very slight injury or none
Mechanism	Circulatory deficiency due to chemical influence	Inhibitory reflex
Development	Progressive	Instantaneous
Appearance	Characteristic	Nothing characteristic
Post mortem findings	Pathological criterion	No pathological criterion
Elements of diagnosis	Clinical and pathological	By exclusion of any pathological causes backed by circumstances preceding death

### Conclusion

My final aim is to emphasize that death by inhibition is an entity. Facts may receive varying explanations but remain essentially unchanged. The medico-legal expert will be confronted with such facts and will be dealing with a special kind of sudden death to which the term "death by inhibition" is rightly given, and which is not readily susceptible to controlled study. Its lack of pathological criteria will never disturb the established reality it may, however, be anticipated that sooner or later advances in pathology may lead to the establishment of final proof. At present it is the duty of the medico-legal experts to keep in mind these facts and give them the weighty consideration to which they are entitled.

I wish to thank Prof. Sydney Smith and Prof. A. Murray Drennan for their keen interest and for placing the facilities of their departments at my disposal.

The Ministry of Health has issued three explanatory leaflets (SDA, SDB and SDC) on superannuation in the National Health Service. They supplement the Ministry's booklet on the superannuation scheme which has already been issued. Leaflet SDA is being sent to local authorities owning hospitals to be transferred under the Act, and it explains the option open to employees transferred under the Act to retain rights corresponding with those enjoyed before transfer. Leaflets SDB and SDC are being sent to voluntary hospitals. The former explains the option open to employees to remain on their present superannuation scheme, and SDC—for employees with not less than 10 years' hospital service before July 5—explains the broad principles which the Ministry of Health will apply when dealing with applications for payments on retirement or death equivalent to those that might have been expected under the voluntary hospital service.

## HODGKIN'S DISEASE · AN UNUSUAL CASE WITH SPINAL SYMPTOMS

BY

O D BERESFORD, MB, M.R.C.P.

*Medical Registrar Southmead Hospital, Bristol*

AND

NORMAN G B McLEITCHIE, MD

*Lecturer in Pathology, University of Bristol*

We record this case because it displays certain less-known features of lymphadenoma which are of greater moment than a mere record of unusual manifestations of a protean disease

### Case History

The patient, a house decorator aged 49, was in good health until October, 1942, when he noticed a swelling of the neck. Clinical examination in December revealed a mass of firm discrete glands in the left side of the neck and supraclavicular region and some smaller glands in the right axilla. No other abnormality was found clinically and the patient felt well. The red cell count, haemoglobin estimation, and total and differential white cell counts were normal. A large cervical gland was removed, and was reported on as a lymphadenoma by Dr Fraser, pathologist to the Bristol Royal Infirmary. Radiotherapy was started in January, 1943, under the late Dr Bryan Adams. (Details of radiotherapy are given in an Appendix.)

In March, 1943, a nodule the size of a walnut still remained in the left side of the neck, but this had disappeared by May, 1943 when no other abnormality could be detected. The patient was examined at three-monthly intervals and was well until August 1946, when he complained of pains in the back and down the right leg. Clinical examination did not reveal any abnormality. Radiological examination did not show tumour involvement of the vertebrae, but osteoarthritic changes were noticed. No treatment was given. One month later the patient was seen again, he complained of having had lower abdominal pains, the character of which suggested girdle pains, and now had loss of power of the right leg and weakness of the left leg. On examination a mass in the right iliac fossa was found with wasting of the right gluteus maximus and of the right hamstrings, weakness of both lower limbs especially the right, spasticity, exaggerated tendon reflexes, and analgesia corresponding to a cord lesion at the level of the tenth dorsal segment. Sphincter control was normal. No further details are available.

Radiotherapy was then directed against the iliac mass and the spinal column between the eighth dorsal and the second lumbar vertebrae. On completion of the course the mass in the right iliac fossa had disappeared. The patient was free from pain but loss of power in both legs was almost complete and he was now incontinent of urine and faeces. He was considered unfit for further radiotherapy and was removed to another hospital, where he was found by one of us to have the clinical picture of a complete transverse lesion of the spinal cord in the lower dorsal region. The cerebrospinal fluid was under normal pressure and showed a normal response to jugular compression. The protein, chloride, and cellular contents were normal, and the globulin and Lange tests were negative. Introduction of 2 ml of lipiodol into the cisterna magna did not demonstrate spinal block.

In January, 1947, a suprapubic cystotomy was carried out and treatment was directed to keeping the patient comfortable. Large bed sores and urinary infection developed and he died three months later—i.e. four and a half years after the onset of symptoms.

### Post-mortem Examination

The body was extremely emaciated and dehydrated. There were large scars in the region of both knee joints and marked talipes equinus. A large bed-sore took up the sacral area, buttocks and lower half of the back, surrounding tissues were thickened and oedematous. No enlarged glands could be palpated and no glands could be found in the cervical supraclavicular axillary or mediastinal regions, or in the abdomen.

A few small soft glands were present at the hila of the lungs and in the inguinal region, these were taken for examination. The structures of the mouth, neck, thorax, and abdomen showed no evidence of lymphadenoma. In particular the liver (2,035 g) showed only a uniform nutmeg pattern, the spleen (130 g) was small and presented a uniform pale red pulp, and section of the ribs revealed a red marrow. Apart from the vertebral column the following were the only abnormalities found.

The lungs showed oedema and hypostatic bronchopneumonia. The heart was flabby and the left ventricle was dilated. There was marked pyelonephritis and cystitis, with slight dilatation of the renal pelvis and ureters, the prostate contained abscesses. No mass was found in the right iliac fossa, but there were slight diffuse adhesions tacking down the caecum. The vertebral column and its integument showed no external abnormality or deformity. Section revealed a uniform sclerosis of the bodies of the seventh and eighth dorsal vertebrae, so that they were harder and paler than those of the other vertebrae but none of the bodies showed any disorganization of architecture.

Removal of the spinal cord revealed no abnormality of the bony canal. The dura appeared normal and not even roughened on inspection with a hand-lens. The pia-arachnoid and nerve roots also appeared normal. The spinal cord showed slight evidence of flattening and softening in the upper lumbar and lower dorsal region. The cranium and the brain and its membranes showed no abnormality.

### Histological Examination

Apart from moderate periportal fatty change the liver was normal as was the spleen. The hilar and inguinal lymph glands showed a subacute inflammatory sinus catarrh. The sclerosis of the dorsal vertebrae was accounted for by a generalized increase of fibrillar connective tissue throughout the marrow, diminished vascularity, and hypoplasia of the cellular elements of the marrow so that they were represented by scanty small round cells. Other vertebrae examined revealed no abnormality. The spinal cord showed a transverse myelitis in the upper lumbar region, a segment of it having large patches of demyelination irregularly scattered in all zones. Sections just above this level showed complete degeneration of the posterior ascending (sensory) columns and sections below showed complete degeneration of the crossed and direct pyramidal tracts. No cellular lesion was found in the cord. These appearances are consistent with a transverse lesion produced by local external pressure.

### The Original Biopsy

Dr Fraser kindly gave us the original slide. The section was from a gland 1.2 cm in diameter and showed the classical features of Hodgkin's disease: there was complete replacement of the normal architecture by a pleomorphic cellular tissue containing the characteristic reticulum cells, some in giant form with or without double nuclei in mirror image form, eosinophilic leucocytes, lymphocytes and plasma cells. The cellular tissue was broken up by a fibrillar stroma condensed into thicker bands in a few places.

### Discussion

While the sceptic might be inclined to consider that the train of events originated with a mix-up in biopsy specimens and ended with a nervous disease complicated by deep x-ray therapy, the findings are not unknown. There are a number of accounts of cases of lymphadenoma with clinical remission from 10 to 36 years (Holmes and Schulz, 1946; Jackson and Parker, 1946). One must therefore conclude that exceptionally with deep x-ray therapy the disease may remain latent for long periods or completely disappear. Our case is remarkable in that we did not find evidence of the disease even in the form of a sclerotic process. It is considered that the sclerosed vertebrae are accounted for by the effects of radiotherapy and if there was previous marrow involvement by lymphadenoma it was not sufficient to disturb the bony architecture. Robinson (1928) reports a similar finding in a case with spinal

## Medical Memoranda

### A Case of Intramedullary Abscess Recovery after Operation

The following case is recorded because of its rarity and because of the successful result achieved by operation and chemo-therapy

#### CASE REPORT

A girl aged 6 was admitted to the Children's Hospital, Tehran, in April, 1945. For a month she had complained of backache and had been suffering from diarrhoea and vulvo-vaginitis. On examination it was found that she had an exaggerated lumbar lordosis and some scoliosis in the dorso-lumbar region. Movements of vertebrae in this area were somewhat limited. This stiffness of the back made walking difficult. No abnormal neurological sign could be found. Radiological examination failed to reveal any bony lesion. She was having an evening temperature of 37.5-38° C. The report on the vaginal discharge, which was repeatedly examined, was "Diverse micro organisms. Gram positive cocci and Gram negative bacilli. No gonococci seen." Diarrhoea and vulvo-vaginitis soon cleared up, but a month after admission, when she was discharged at her mother's request, she still complained of pain in her back.

Seven months later (Dec. 22, 1945) the girl was readmitted. According to her mother the backache had gradually become worse and vulvo-vaginitis had recurred. On examination it was seen that the general condition was poor and walking very difficult. The vertebral column was kept absolutely rigid, with severe lumbar lordosis. There was left foot drop. The left knee-jerk and both ankle-jerks were absent. No sensory impairment was found. Her evening temperature was 37.5-38° C. Radiographs of dorso-lumbar vertebrae were again normal.

"Oestroform" and vitamin B injections were given without benefit. On Jan. 25, 1946, she was dragging both her feet, and on Feb. 4 there was complete flaccid paralysis of the right lower limb. On Feb. 7 she was put on systemic penicillin therapy—100,000 units were given in three hourly doses of 10,000 units. The vulvo-vaginitis completely cleared up, but there was no change in her paralytic condition. On Feb. 17 the left lower limb was also completely paralysed and she was complaining of severe pain in her back. Superficial and deep sensations were greatly diminished in both lower limbs. There was retention of urine, but the urine was normal. The white cell count numbered 13,400 (88% polymorphs).

A course of sulphathiazole was started, and within two days a definite sensory level was established and the backache completely

disappeared. Below the level of the first lumbar segment sensation to touch was lost. Pin-prick sensation was also absent except for a small area in the anterior aspect of both thighs. There was faecal incontinence as well as urinary retention with overflow. A radiograph of the spine again showed no abnormality.

In view of the possibility of some infection in the lumbar region, lumbar puncture had not been performed until this date. Puncture was done on Feb. 23. A few millilitres of golden yellow fluid under low pressure was obtained. Albumin, 0.85 mg per 100 ml. 20 mononuclear cells per cmm., no micro organisms. Two days later a descending myelography was performed. "Ioditol," 2 ml., was injected through a cisternal magna puncture. As is shown in the accompanying radiograph the opaque substance did not pass below the level of the upper border of the eleventh dorsal vertebra.

The parents were reluctant to consent to an operation, but on March 10 permission was obtained. By this time the patient's general condition was very poor and paralysis of the lower limbs complete.

**Operation**—Open ether anaesthesia was administered. The eleventh and twelfth dorsal laminae were removed. The dura mater was tense, it was carefully incised in the middle line. The cord presented all the appearances of an intramedullary tumour, and had completely filled the canal. In the lower reaches of the opening there were some fibrinous deposits on the nerve roots. On palpation of the cord with two fingers distinct fluctuation could be obtained. The swelling was aspirated exactly in the middle line and 3.5 ml of frank pus withdrawn. Penicillin, 20,000 units, was introduced into the cavity, but most of it escaped from the puncture spot into the theca. The cord did not completely collapse, and it was thought that this was probably due to oedema. As the patient's condition was unsatisfactory the wound was hurriedly closed. The opening in the dura mater was not sutured. The pus contained a large number of leucocytes, but no micro organisms could be found. Culture and guinea pig inoculation were also negative.

On the third day after operation the patient felt the needle prick in the left buttock when receiving penicillin—10,000 units three-hourly were continued until the seventh day. On the fifth day she could just move her left thigh. On the ninth day stitches were removed but from one of the stitch holes a few drops of cerebrospinal fluid escaped. The amount gradually increased and the wound had to be reopened on March 21.

The spinal cord was again examined, and fluctuation could still be obtained. This time a larger-bore needle was used for aspiration, and 4 ml of pus identical with the first specimen was withdrawn. On this occasion the cord collapsed completely, but there was a hard nodule, the size of a split-pea, situated near the end of the exposed cord. Penicillin was again injected into the cavity of the abscess. The muscular layers were sutured with care. The wound healed without any further difficulty.

Sensation and movements slowly returned to the paralysed limbs. On the anterior aspect of the left thigh there was severe hyperaesthesia for some days. Sphincter disturbances also gradually cleared up. A month after the first operation her micturition, and ten days later the defaecation, were under control.

Two months after the first operation she could walk if some one would hold her hand. On Aug. 28, 1946, five months from her last operation, she walked without any difficulty, but her gait was somewhat waddling. In walking, both feet were held in the valgus position. She had no backache and had gained 3 kg in weight. Her general condition was excellent.

Muscular power of the limbs was good except for some weakness of the anterior tibiales. The left knee-jerk was weak. Both ankle-jerks were still absent. The left plantar reflex was flexor but the right was doubtful. Sensation to touch, pin-prick and position was normal.

#### DISCUSSION

An abscess within the spinal cord is a rare condition. Woltman and Adson (1926) published a case of their own and gave a summary of 29 other cases reported in the literature up to that date. P. K. Arzt (1944) in a review of the literature was able to find 39 cases, including the 29 already referred to. He discussed all aspects of this disease at length and added three cases of his own.

Prognosis in this condition seems to be very poor. Only four cases have been treated successfully by operation, but in one of them paraplegia did not improve. Six other cases were also submitted to operation, but the outcome was in all other cases was fatal.

In the majority of cases reported a primary focus of infection had been found. In the above case it is possible that micro-organisms entered the circulation from the known focus of vulvo-vaginitis. In Uhlmann's case, in which multiple intramedullary abscesses were found, the primary focus was a gonococcal urethritis.

In none of the surgically treated cases had chemotherapy been tried and the successful result obtained in my case is probably largely due to penicillin and sulphathiazole medication.

My thanks are due to Mr. Brodie Hughes, surgeon in charge, Neurosurgical Department, Birmingham United Hospital for his advice and encouragement in the final preparation of this paper.

Woltman, H. W. and Adson, A. W. (1926). *Brain* 49: 193.

He first describes the theory and rationale of specific remedial exercises. He covers the field exhaustively but unfortunately his classification is neither clear nor simple. He would do well in future editions to prune these chapters of old-fashioned terminology that has no practical relation to the advanced theories that he teaches. In two chapters Mr Fitton describes the relation of specific remedial exercises to the pathological changes after injury and to splints and plaster casts. The latter will be of great interest to plaster-room assistants and after-care sisters. Mr Colson then discusses the theory behind exercises with special remedial apparatus and describes the various types with their advantages and disadvantages. He is enthusiastic about using a pulley-and-weight system for re-developing muscles. He does not like other types of weight-resistance exercise though it is noteworthy that very dramatic results can be obtained in certain types of case by using the de Lorme system. In subsequent chapters he describes exactly the remedial exercises to be used in all the various types of bone injury though strangely enough he does not mention torn ligaments of the knee joint. These graduated routines are lucidly and neatly arranged in tables after an explanation of the aims of treatment at various stages. He subdivides the aims into primary and secondary—a very useful classification—reminding the physiotherapist and remedial gymnast of what is most important. Dr Langdale Kelham then contributes a short but excellent chapter on the treatment of amputation stumps. The book concludes with a neat account of re-education in walking. The lay-out and the illustration of the book are excellent. There is no doubt that it should be studied by all who are concerned with the treatment of injuries of the spine and the extremities.

## INSTRUCTION IN PSYCHOLOGY

*Psychological Atlas* By David Katz (Pp 142 396 illustrations 55 00) New York Philosophical Library, 15 East 40th Street

Any teacher called on to provide classes of instruction in psychology and elementary psychiatry is likely to find this a useful book. It contains 395 illustrations, excellently reproduced with verbal descriptions in the earlier part of the book. Many of these illustrations could be suitably reproduced as slides for exhibition to a class of students. The subjects covered include the anatomy and physiology of the central nervous system, optical illusions, perception and gestalt phenomena, the apparatus for and the results of experiments on memory, work and fatigue, symbolism, with illustrations from picture writing, Chinese idiograms, and Egyptian hieroglyphs, facial expression and physiognomy, constitutional types, child psychology, psychological testing, abnormal psychology, occult phenomena, animal psychology and conditioned reflexes. At the end are some 40 photographs of distinguished psychologists. Many of the pictures are in themselves unusual and would be difficult to come by but are apt illustrations of particular aspects of the general theory which the teacher will be trying to expound. They are nearly all of a kind to awaken interest.

ELIOT SLATER

The sixth edition of Prof Cameron's remarkable little book, *Recent Advances in Endocrinology* (J and A Churchill, 21s), follows only two years after the fifth. To repeat in different words the praises earned by previous editions seems unnecessary after so short an interval. If there are still any doctors who have omitted to buy the fifth edition, they should immediately retrieve their mistake by buying the sixth. Possessors of the fifth might be well advised to wait for a few months and buy the inevitable seventh for there have been few advances in the last two years of sufficient importance to warrant inclusion. The new material includes an excellent short account of the uses in diagnosis and treatment of radioactive iodine and of the production of artificial iodoproteins with a thyroid-like activity. There are a few omissions which might well be made good next year. Recent workers on exophthalmos lay more stress on the increase in retrobulbar fat than on oedema of orbital tissues. The section on prolactin does not very adequately reflect modern views on the action of the pituitary in lactation. There is a most curious omission of any mention of Verney's work on the posterior pituitary and the effects of anxiety on water metabolism. Two suggestions might be considered while the next edition is in preparation—a more detailed index and a section summarizing all new material, with references to the main body of the book.

## BOOKS RECEIVED

*The Clinical Picture of Thyrotoxicosis* By Peter McEwan M A, MB Ch B, FRCS Ed (Pp 125 15s) London Oliver and Boyd 1948

A general account of thyrotoxicosis, including its diagnosis and treatment

*Medical Education* By Ffranceon Roberts, M D (Pp 172 12s 6d) London Lewis 1948

An account of the training of students and teachers

*Diagnostic Bacteriology* By I G Schaub A B, and M K Foley, A B 3rd ed (Pp 532 22s 6d) London Kimpton 1947

A laboratory textbook on the isolation and identification of pathogenic bacteria

*Letters on Yellow Fever Addressed to Dr William Currie* By Noah Webster (Pp 110 52 00) Baltimore Johns Hopkins 1947

With an introductory historical essay

*The Worker and the State* By Sir Frank Tillard CBE M A M Com 3rd ed (Pp 302 16s) London Routledge 1948

An account of modern social legislation

*Medecine Légale Judiciaire* By C Simonon 2nd ed (Pp 819 1,100 francs) Paris Maloine 1947

A textbook of forensic medicine

*An Introduction to the Principles and Practice of Homoeopathy* By C E Wheeler, M D, BS, BSc 3rd ed (Pp 371 21s) London Heinemann 1948

Intended for those who wish to form an unbiased opinion of the claims of homoeopathy

*The Conflict of Science and Society* By C D Darlington FRS (Pp 51 2s) London Watts 1948

The 1948 Conway Memorial Lecture

*Recent Advances in Surgery* By H C Edwards CBE, MS FRCS 3rd ed (Pp 437 24s) London Churchill 1948

An account of modern surgical practice

*Constitutional Medicine, Endocrinology and Allergy* Edited by E Pulay, M D, and P Lansel M D Vols 2 3 and 4 (Pp 102, 63, and 112 10s 6d each) London Muller 1948

Papers by various authorities

*Psychiatrie et Psychologie* By M Assouly and others (Pp 47 145 francs) Paris Administration Synthese et Thérapeutique 1948

Papers on various aspects of medical psychology

*Diseases Affecting the Vulva* By Elizabeth Hunt, BA M D Ch B 3rd ed (Pp 211 25s) London Kimpton 1948

Much new material on treatment has been added

*Hemoglobin, Plasma Protein, and Cell Protein* By G H Whipple, M D (Pp 27 7s 6d) Illinois Thomas 1948

A monograph on the production and interchange of these proteins

*Fungal Diseases of the Lungs* By David T Smith, M D (Pp 59 10s 6d) Illinois Thomas 1948

A monograph, with references

*Nutrition and Hormones* By Leo T Samuels Ph D (Pp 48 8s 6d) Illinois Thomas 1948

A monograph on the relation between the endocrine glands and nutrition

*Embryonic Sex Hormones and Sexual Differentiation* By Carl R Moore, Ph D (Pp 81 10s 6d) Illinois Thomas 1948

The experimental effects of sex hormones

*Pain* By Harold G Wolff, M D, and Stewart Wolf, M D (Pp 86 10s 6d) Illinois Thomas 1948

A discussion of various types of pain in man

those who believe that some of the impurities present in most preparations have a considerable therapeutic value, certainly it was a fairly uniform opinion in the U.S.A. that after April, 1945, results tended to become poorer and poorer and that this may have been due to a preponderance of penicillin K, which is relatively ineffective against the spirochaete. In spite of its excellent effect on signs and symptoms it seems at least doubtful if penicillin is as effective in reversing positive serum reactions as a combination of arsenic and bismuth, whether this is of great importance is a matter of opinion, but most of us, and patients too, are encouraged by a regular and rapid fall in the titre of positive reactions, and in latent syphilis this is the only yardstick by which the effect of treatment can be measured.

Much remains to be learnt about the penicillin treatment of syphilis: whether a continuous moderate blood concentration is better than a series of peaks, whether one heavy course is as good as several moderate ones, and whether and when courses should be repeated (in the absence of signs of serological or clinical relapse). Most relapses in early syphilis occur within six months of completion of treatment, so that it would seem reasonable, when relying on penicillin alone, to give a second course within three months or so of the first, just as has been the custom with arsenic and bismuth in the past. As to the effect of penicillin in late syphilis few would care to express an opinion, time alone will show, and it will be five years at least before we know whether those patients treated for early syphilis with penicillin only are going to develop such late manifestations as tabes and G.P.I. The one great advantage of penicillin is the absence of serious side effects. Apart from Herxheimer reactions, which are very common but rarely serious, and urticaria, which is uncommon and seldom an indication for discontinuance of treatment, there are no contraindications to its use, and doses may be stepped up to very high levels, though it seems doubtful whether such doses are ever necessary. Methods of treatment are still being frequently changed, and the wise syphilologist will keep an open mind till some general agreement is reached.

## OSTEOARTHRITIS OF THE HIP-JOINT

Osteoarthritis of the hip-joint commonly has as its starting-point a congenital malformation, a developmental abnormality of childhood and adolescence, or a traumatic lesion. Physical treatment is an important palliative measure, but cannot result in cure. Injection into the joint of various fluids intended to modify the chemical reactions of the synovia has aroused interest, but as yet there are no carefully documented reports of the long-term effects in any considerable series of cases. Surgery will therefore continue to play a large part in the relief of pain, the correction of deformity, and the restoration of mobility.

For single osteoarthritic hips, arthrodesis has generally been accepted in Great Britain hitherto as the most reliable method of treating intractable pain and correcting deformity, and for this purpose the two-stage method of Watson-Jones<sup>1</sup> has gained in popularity. Arthrodesis sacrifices

joint mobility but allows much greater activity because of the relief of pain and deformity. In a case of bilateral osteoarthritis of the hip the restoration of mobility in one or both joints is a pressing additional necessity. Valuable recent reports on reconstruction operations have been published by Bristow,<sup>2</sup> McMurray,<sup>3</sup> Plewes,<sup>4</sup> and Girdlestone.<sup>5</sup> More or less wide excision of the femoral head while often sacrificing stability, has given relief of pain and increased mobility. McMurray's operation of realigning the weight distribution by intertrochanteric osteotomy gives benefit also by correcting the deformity, though without improving movement at the joint. Fresh interest has been aroused in the reconstruction of osteoarthritic hip-joints by the report given by Smith-Petersen<sup>6</sup> at Exeter to the British Orthopaedic Association on the results of his arthroplasty operation, first described in 1939. In the past the effects of arthroplasty have often been vitiated in these cases by shock, by infection, and by new bone formation around the newly constructed joint. Smith-Petersen employs an antero-lateral approach which is practically bloodless, and by meticulous care and gentleness of handling gains easy access to every component of the articulation. The acetabulum and femoral head are reshaped with specially designed tools and the capsule and synovial membrane are widely excised. A suitably shaped cup of vitallium or of 18/8 stainless steel is then inserted. The operation is followed by a carefully planned programme of after-care. It should be stated that there are surgeons in this country who prefer to use the original Murphy lateral approach with elevation of the great trochanter. They claim that muscular re-education is easier and that by avoiding the wide denudation of the ilium they minimize the risks of new bone formation.

Herman Gade<sup>8</sup> has now reviewed the whole problem of osteoarthritis of the hip-joint, and he describes 130 operations of various kinds carried out by him in Norway between 1938 and 1946 on 115 patients. Among these operations are 12 involving total excision of the capsule, 14 arthroplasties by the Smith-Petersen vitallium cup method, 49 operations "combining both these procedures," 7 arthroplastic resections without the insertion of a cup, and 27 arthrodeses. It is a little difficult to understand the reason for Gade's separation of the "combined operation." Excision of the capsule and synovial membrane of the hip-joint is an essential feature of Smith-Petersen's arthroplasty, as it was indeed of the original fascial arthroplasty described by Murphy many years ago.<sup>9</sup> The synovial membrane and capsule of the hip-joint both play an important part in the symptomatology of osteoarthritis, a fact that has been stressed by Tavernier<sup>10</sup> and his associates at Lyons, who have advocated a denervation operation for this reason.

In evaluating operative results the clinical assessment of functional restoration is difficult. Ferguson and Howarth<sup>11</sup> measured the total normal range of hip movements in degrees and multiplied this figure by a factor which gave an index of 100. The range of movements in a stiff hip multiplied by the same factor gave a percentage figure. Along similar lines Gade uses a different factor for different sectors of each direction in the range of movement at the hip, and provides an index of functional value which

s interesting, though it must be rather more complicated to apply. In 54 cases in which cup arthroplasty was performed the average age was 45, and the follow-up period averaged nearly four years after operation. Where the capsule was not excised relief of pain was obtained in 41% of cases, as compared with 78% of those in which there was capsular excision. In the first group the functional result was assessed at 56%, with a post-operative gain of 20%, while in those cases with capsular excision as well the figure was 66%, with a post-operative gain of 28%. An important late finding was atrophy of the bone ends (both acetabulum and femoral head), which Gade attributes to pressure from the metal cup. This change was seen more frequently where the joint surfaces were atrophic at operation. In 34 of the 54 cases there was some degree of new bone formation around the cup, in 8 of them to such a degree as to affect the results adversely. Gade concludes that in relieving pain and increasing mobility Smith-Petersen's cup arthroplasty with capsular excision yields results which have probably never been bettered by any previously used method of arthroplasty. Commenting upon the large number of cases operated upon by this method and the paucity of reported results, Gade says that this is probably due to the fact that such results can only be estimated after long observation. He applies this to his own work and will not commit himself to a final opinion upon the likely duration of his results, in which the most serious complication, he suggests, is atrophy of the bone ends.

Those surgeons in Great Britain who are following Smith-Petersen's technique of cup arthroplasty are clear that relief of pain is a most satisfactory and early result, and that correction of the deformity is complete without any additional operation. They will also agree with Gade that the range of movement obtained depends on painstaking care in after-treatment. The competence of the muscular apparatus of the hip before operation has an important bearing on the probable result. Smith-Petersen has emphasized repeatedly the need for operation before muscular degeneration has proceeded too far. For this reason Smith-Petersen himself has operated on some of the very early cases of osteoarthritis seen in young adults suffering, for example, from the effects of imperfect reduction of congenital dislocation of the hip. Encouraging as his early reports seem to be, it is obviously going to be many years before a true assessment can be given. There remain two problems in the successful surgical reconstruction of the osteoarthritic hip. First there is the difficulty of re-establishing an efficient local neuromuscular system, and, secondly, there is the later difficulty of maintaining biologically what has been achieved temporarily as a mechanical compromise. How long will the local equilibrium remain undisturbed by the presence of a foreign body?

## REMUNERATION OF GENERAL PRACTITIONERS

In a letter on this subject in last week's issue of the *Journal* (p. 110) it was estimated that the proposals for remuneration under the National Health Service might result in a loss to a group of local practitioners of more than 50% of their present income from general practice. The group comprises ten general practitioners in a rural area with a population of 10,000, and in each of these practices the income received from the present panel capitation fees amounts to less than one-quarter of the gross receipts. The estimated loss is based on the assumption that the capitation fee will be about 15s. The capitation fee will be the main source of public remuneration for general practitioners, but certain additional payments may be overlooked in making comparisons between present and future prospects.

The Government's proposals provide for the establishment of a central fund of some £40.8 million, which corresponds to a capitation fee of 18s. for 95% of the civilian population. To the extent to which the proportion of the population signing on a doctor's list is less than 95% the capitation fee—disregarding basic salary—per person on a doctor's list will be higher than 17s. 5d. (i.e., 18s. less the mileage apportionment). This central fund will provide in the first place for payments for mileage. The sum allocated for this purpose is £1.3 million as compared with the pre-war mileage fund of £250,000 and the existing mileage fund of approximately £600,000. It will also provide a fixed annual payment of £300 a year in those few cases in which this is applicable, and the remainder will be distributed to each executive council for local distribution in the form of a capitation fee for each person on each doctor's list.

Apart from this central fund, however, there will be an additional amount to be distributed of over £4 million, or approximately £200 per general practitioner in the Service. Furthermore, over and above the capitation fee there will be available to general practitioners income from any one or more of the following sources: (1) The sum of £400,000 a year will be available for providing discretionary extra 'inducement' payments to assist doctors practising in 'peculiarly difficult (e.g., sparsely populated or unpopular) areas.' The Minister will consult the Medical Practices Committee on the distribution of this sum. (2) There will be a grant for supervision of the training of assistants amounting to £150 per annum. (3) Fees for maternity services: seven guineas a case will be paid for maternity services to practitioners on the "obstetric list" and five guineas a case for practitioners not on the list. (4) There will be additional payments in respect of drugs and appliances which a doctor is required to supply on the spot. The rate will be 2s. 6d. per annum (or more in certain years) for every 100 persons on the doctor's list. (5) Where the doctor dispenses by arrangement with the executive council payments for drugs, etc., will be made either on the basis of the actual drugs and appliances he supplies or at a flat rate per annum in respect of each person on his list, with additional payments for specially expensive items. (6) The Government superannuation contribution of 8% of the net remuneration of each general practitioner must be taken into account. (7) Sessional fees from local health authorities will be paid—for example for clinic appointments. (8) General practitioners may provide general medical care as members of the staff of a hospital in the following capacities: (a) as one of the staff of a general practitioner ("cottage") hospital, (b) as the part-time medical officer of a convalescent home or other institution. For these appointments remuneration will be received

from the hospital management committee (9) Fees from private practice will continue. In addition the practitioner will receive yearly  $2\frac{1}{4}\%$  interest on the capital value of his practice as estimated for the purpose of compensation.

### THE SHORT OESOPHAGUS

Rare diseases are apt to become more common when their possibility is kept in mind, and this is particularly true of hiatus hernia, short oesophagus, and the peptic ulceration of the oesophagus commonly associated with it. The protean manifestations of oesophageal hiatus hernia provide a common ground for many specialists. Obscure cases of anaemia, unexplained haematemesis, dyspepsia of all degrees from heartburn or "wind in the stomach" to intense boring pain related to meals, dysphagia, pain simulating angina but not related to exercise, breathlessness, and cough may all be the result of herniation of the stomach through the oesophageal orifice of the diaphragm. Unless the radiologist considers the possibility of the condition he may miss it by using routine radiological technique, and it is therefore the physician's responsibility to draw his attention to it.

There are two types of hernia: those with a short oesophagus and a pouch of stomach drawn up into the chest, and those with an oesophagus of normal length and herniation of part of the fundus of the stomach. It has been assumed that short oesophagus was a primary developmental error in its caudal passage, the stomach failing to reach the sanctuary of the abdomen before the fusion of the diaphragm. On the other hand, herniation with a full-length oesophagus was thought to be due to a primary defect of the diaphragm. It has been recognized that peptic ulcer of the oesophagus is particularly associated with the short oesophagus, and Dick and Hurst<sup>1</sup> demonstrated the ease with which gastric juice regurgitates through the vertical opening between the short oesophagus and the gastric pouch. Regurgitation is less apt to occur when the opening through the cardia is normally oblique and the oesophagus of full length. The division of aetiological responsibility between developmental error of the diaphragm and faulty descent of the oesophagus and stomach has recently been discussed. Allison, Johnstone, and Royce<sup>2</sup> pointed out that peptic ulcer of the oesophagus, if it persists for any length of time, is associated with shortening of the oesophagus from cicatricial contracture, as occurs with the "purse stringing" of the lesser curve from gastric ulceration. Gilbert, Day, and Rall<sup>3</sup> consider that shortening from spasm of the longitudinal coat of the oesophagus from a vago-vagal reflex may be responsible for the drawing up of a gastric pouch. Experiments on dogs and rabbits have shown such shortening after vagal stimulation, and the same result was obtained by stimulation of the peritoneum, distension of the gall-bladder, and manual distension of the stomach wall. Vagal section or administration of atropine abolished the reflex. They draw attention to the apparently high proportion of intra-abdominal lesions which may be associated with hiatus hernia. The weakness in their clinical argument is the lack of a control series in the corresponding age groups, and it may be suspected that cholelithiasis, obesity, and duodenal ulcer are found as often in people without an oesophageal hiatus hernia.

The conceptual unity of the mechanism of short oesophagus and hiatus hernia has been propounded by Smithers<sup>4</sup> and by Allison<sup>5</sup> in his recent admirable paper on peptic ulcer of the oesophagus. After careful study of 63 patients

Allison maintains that short oesophagus is usually an acquired condition due to defects in the diaphragm which allow an intermittent or persistent herniation of the stomach into the thorax. This facilitates regurgitation of acid gastric juice into the oesophagus, leading to peptic oesophagitis or peptic ulceration, the cicatricial reaction causes further shortening of the oesophagus. Smithers believes that spasm of the longitudinal muscle fibres is particularly important. A natural weakness of the oesophageal hiatus may be aggravated by increasing abdominal pressure from obesity, or by atrophic changes in muscle with advancing years. Fifty-six of the 63 cases were in fact over 50 years of age. During inspiration the negative suction in the chest and the positive pressure in the abdomen both increase, so there is a natural tendency for the cardia to be drawn upwards or, alternatively, for the stomach contents to pass into the oesophagus. But it is at this time that the crural fibres contract round the lower end of the oesophagus, closing its lumen and normally preventing herniation. The muscular contraction is not equal in all directions, being strongest at the sides, moderate in front, and weakest behind—a point of great importance in relation to operative repair of the hernia. Although Allison admits that a true failure of longitudinal development of the oesophagus may occur, it must be exceptionally rare, and for practical purposes cases of hiatal hernia and short oesophagus, with or without ulceration, may be considered as due to a primary defect of the diaphragm.

The logical application of this viewpoint is to use a more radical surgery to cure the deformity, which may allow acid to regurgitate into the oesophagus causing oesophagitis and ulceration. In most cases symptoms are not sufficiently severe to justify operation, but there are a few that may be greatly benefited by either repair of the orifice or excision of the cicatrized area. Repair of the hernia was undertaken in 9 of the 63 cases in Allison's series and a further 5 had excision of the ulcerated and badly stenosed oesophagus with anastomosis to the jejunum.

### NODULAR DEFENSIVE REACTIONS OF THE SKIN

The "trisympomatic malady of Gougerot" is a characteristic skin reaction which consists of three well-defined lesions—erythematous papules from 2–10 mm in diameter, resembling most often erythema multiforme or sometimes urticaria, purpuric macules from 1–5 mm, and small firm nodules from 2–7 mm, varying in their depth in the skin. Gougerot<sup>1</sup> has recorded six cases. The lesions come out in crops over the whole body, but especially on the lower limbs, and disappear in 15–60 days, usually without any scarring. The condition persists for years and may be symptomless or associated with very occasional pyrexia, headache, and joint pains. The general health is fair, though the patient may gradually lose weight and feel fatigued. Histologically, the lesions are situated in the dermis and there is obvious swelling of the endothelium of the capillaries, which are surrounded by a sleeve of fibrinoid necrosis and marked polymorphonuclear infiltration. Despite extensive studies no pathogenic agent has been found in either the blood or the tissues.

Gougerot suggests that this syndrome is one of a large series of skin reactions which are caused by organisms establishing themselves in a sensitized skin. They vary from acute necrotic tuberculides to the lesions described above, and include other tuberculides and "pityriasis lichenoides varioliformis acuta". He has labelled them nodular dermal "allergides". Closely related to them are Osler's

<sup>1</sup> Dick R. C. S. and Hurst A. *Quart J Med* 1942 11 105

<sup>5</sup> Allison, P. R. *Thorax* 1948 3 20

nodes, which are associated with severe endocarditis, here Gougerot believes the cutaneous defence reaction is inadequate. Numerous pathogens may cause these nodular dermal "allergides," including the tubercle bacillus, pyogenic cocci, and, less often, Hansen's bacillus, gonococci, trichophyton, and other organisms known and unknown. He considers that it is justifiable to group these reactions together, as they all entail the same allergic process, which he calls the nodular defensive reaction. Not only does he think the skin is the site of this reaction but he suggests that it takes an active part in defence against organisms by complex mechanisms and notably by tissue secretions.

While a relation between many of these conditions can be seen, it is probably spreading the net of allergy too wide to include such lesions as Osler's nodes unless we are to assume that all inflammatory processes are allergic. There is moreover insufficient evidence that organisms occur in the blood in such a condition as erythema multiforme, even in the six cases which Gougerot has himself described. It would be more helpful to isolate conditions in which the aetiology is known than to group together large numbers of eruptions in which the pathogenic causes can only be surmised. It is unjustifiable to assume that the lack of resistance in endocarditis with Osler's nodes is due to failure of the skin defence mechanism and it is usually considered that the cutaneous reaction of a tubercle is an indication of a good resistance and not the cause of it.

### GIANT HYPERTROPHIC GASTRITIS

The normal gastric mucosa is subject to wide variation, both between different people and in the same person at different times. Only changes in its gastroscopic or radiological appearances that are constant, or, if inconstant, when accompanied by symptoms, can be regarded as pathological. Giant hypertrophy of the gastric mucosa fulfils these criteria. It is a rare condition, and in reporting six new cases Maimon<sup>1</sup> and his associates refer to fewer than fifty cases reported in the literature.

There is no constant clinical picture, but all six patients had epigastric discomfort. One patient had had a severe haematemesis, this has occurred in other cases, and Bourne<sup>2</sup> has reported in Britain an example in a man who had severe anaemia. Radiologically the rugae are prominent and rigid, collections of barium between the elevations of the mucosa give the impression of multiple polyps, and in some cases true polyps may occur, as Sprigg<sup>3</sup> has shown. Gastroscopically the appearance varies, but usually the dull red oedematous and infiltrated folds can be seen, there may be superficial ulceration, and in all cases the distinction from carcinoma may be impossible. Macroscopically the rugae are seen to be enlarged and tightly packed together, so that the resemblance to the cerebral convolutions may be striking, sessile polyps may also be present. Microscopically, redundancy of the mucosa with marked hypertrophy of the glandular structures are the outstanding features. In some areas there may be cyst formation, with metaplasia to the intestinal type of epithelium.

Little is known of the aetiology of the condition. It is uncertain whether the cause is inflammation, and the condition would therefore be better given the descriptive name of giant hypertrophy of the gastric mucosa rather than giant hypertrophic gastritis. Its importance lies in its relationship to carcinoma, for it has been suggested that it may

be a precursor of a neoplastic change, but this again is not certain. What is certain is that both gastroscopically and radiologically it may be impossible to differentiate between this condition and carcinoma of the stomach. Gastrectomy is therefore the treatment of choice.

### COLOUR TERMINOLOGY

The publication of a report on colour terminology by a committee of the Colour Group of the Physical Society<sup>1</sup> marks the end of an inquiry which has been proceeding since 1941. The compilers have gone beyond the accepted uses of colour in physiology and colour physics and have attempted, first, to collect information on existing usages in a variety of industries, and secondly to decide on the minimum changes necessary to secure a consistent terminology that could be used by all colour workers. Physiology, as might perhaps be expected, comes well out of this scrutiny. The terms used to describe deficiencies of colour vision are definable in terms of experimentally determined characteristics, and though associated historically with the Young-Helmholtz theory of colour vision they will probably remain undisturbed by such work as, for example, that of Prof. Hartridge on the reality of a fourth and separate yellow-sensation.

It is rather in usages regarded as normal or "everyday" that some degree of restraint is required from professional men, as was lately shown by the Colour Group at the expense of visitors to the Physical Society's Exhibition. Confronted with one particular colour sequence and asked to describe the quality in which there was variation, just under one thousand visitors proposed between them some 43 different terms. As an example, the word "shade" may be used in at least four different senses. It is used in ordinary speech to mean any colour, by the dyer as a synonym for hue (the subjective equivalent of dominant wavelength), in the paint industry to describe a small variation in "tone" from another colour, and, correctly, by the printer for the shadow effect given by a darker colour of the same hue and saturation as another. Tone and brightness provide other examples of uncertain meaning, and in the case of the latter it is proposed that the colour physicist should himself promote understanding by giving way. Unquestionably when we refer to the brightness of our neighbour's front door we have in mind not merely the intensity of the light which is scattered from its surface but also the vividness of its colour. Apart from this general and almost instinctive use the matcher of dyestuffs uses brightness to describe the opposite of that dullness which results from the addition to any colour of a small quantity of a neutral grey. It is proposed, therefore, that the physicist should renounce his use of this term and that the word "luminance," already proposed for the objective measurement of luminous intensity, should be joined by "luminosity" as the corresponding subjective term to indicate "intensity of luminous sensation."

It would be well for mutual understanding if the committee's recommendations could be generally followed, for the number of changes required of individual users is comparatively small. In place of 230 existing usages it is suggested that 60 should suffice for unambiguous description "throughout science and industry."

On July 8 Lord Webb-Johnson was re-elected President of the Royal College of Surgeons of England for the eighth successive year.

## HOSPITAL ADMINISTRATION IN AMERICA

### REPORT TO KING EDWARD'S HOSPITAL FUND

Capt J E Stone, who lately undertook a tour of the hospitals of the United States and Canada on behalf of King Edward's Hospital Fund for London, has presented to the Fund a report on some of the latest ideas and devices in hospital administration and equipment which he discovered on the other side.

His general impressions are that the hospitals in the large cities of America are much bigger and more massive in appearance than those in Britain. The majority are of the multi-storied type, not because of limitations of ground space, but to reduce horizontal travel. He specially noted the large, light, and lofty entrance halls, some of them bigger than our own out-patient departments, and conveying a feeling of welcome often absent from British hospitals, even modern ones. A visitors' lounge, comfortably furnished with armchairs and small tables and decorated with flowers, often opens off the main entrance.

The popular building material is glass bricks, which increase the lighting without loss of privacy. Stainless steel is chosen for equipment everywhere. If an item can be obtained in this material no other will serve. All kinds of devices are used for saving labour—dictaphones, stenotyping machines, electric typewriters, pneumatic tubes for carrying documents, the teleautograph system for the transmission of messages, electric scrapers, polishers, and the like.

The public wards are rather larger in America than is customary in Britain, but there is now a tendency towards smaller ones and to a division of the original almost square ward into several compartments by the use of curtains. Three types of accommodation are commonly provided: private (single-bed rooms), semi-private (two bed rooms), and general or public wards (10 to 26 beds). The majority of patients are able to pay for their maintenance, and because of this the proportion of private bed accommodation is relatively high in practically all hospitals accounting for a quarter or a third of the total bed accommodation. An increasing number of people are making provision for hospital care by means of an organization which corresponds to British contributory schemes. Staff is plentiful except for nurses. The nursing position in America appears to be similar to that in Britain.

### Hospital Bed Ratios

The method of calculating the number of beds required for a given area has been worked out in New York as a result of an analysis which shows that for the past ten years an average of 120 patient-days of general hospital care has been provided for each death occurring in the city. From this a formula has been developed which indicates that 0.41 general hospital beds should be available for each death occurring in one year in a population group.

The U S Public Health Service recommends the following as adequate:

General hospitals 5.5 beds per 1,000 population (or from 3.5 per 1,000 in sparsely populated areas)  
Chronic disease hospitals 2 beds per 1,000  
Mental hospitals 5 beds per 1,000  
Tuberculosis hospitals based on the average annual death rate from tuberculosis

Public Health centres 1 per 30,000 population (or up to 1 per 20,000 in States with fewer than 12 persons to the square mile)

The authorities are very definite that no hospital should exceed 1,000 beds, the majority place the maximum at 700 to 800.

Several American authorities expressed the opinion that the day of the isolated specialist hospital is over and that if these hospitals are to render efficient service in the future they must work in close association with medical centres of general hospitals. The tendency is towards making the large general hospital complete in every respect so far as all specialties are concerned. A large number of hospitals in country districts are of the 100-bed class, all voluntary, and all complete in the sense that they meet the needs of all classes, providing private rooms and public wards.

It is estimated that from 5 to 15% of the beds in a general hospital should be for children. The Americans lay stress on the individual care needed by children to protect them from cross-infection.

The following points among others are laid down in connexion with the siting of hospitals:

Ample parking space, present and prospective

Good light in adjacent roads

Avoidance of noise from highways, railroads, playing grounds

Avoidance of insect infested areas

If there are industrial smokes in the vicinity the hospital must be out of line of prevailing winds

A cemetery should not be visible from the hospital

One of the minimum standard requirements for hospitals desirous of approval by the American College of Surgeons is that the hospital should provide a clinical laboratory giving a complete and properly supervised service. This laboratory is expected to be able to cope with the essential examinations immediately necessary in assisting the clinician in making or confirming his diagnosis—e.g., urine analysis, blood counts, smears, sputum examinations, and spinal-fluid counts. The American hospitals, both large and small, are proud of their laboratories, which are generally well equipped and adequately staffed.

### Operating-theatres

It is generally agreed that there should be one operating-theatre for every 40 or 50 surgical beds. In small hospitals there should be one major and one minor operating-theatre in addition to an emergency room in the admission department. Generally the standard lay-out comprises twin theatres with a "scrub up" between them and a sterilizing room similarly placed. Opinions differ as to the provision of anaesthetic rooms, some hospitals have dispensed with them. In one hospital the operating theatre unit consists of seven theatres ingeniously arranged around a central work area, economizing space, time and effort. The entrance for patients is from an outside corridor, thus avoiding cross traffic and there are no anaesthetic-rooms. It is estimated that the theatre floor space should be approximately 30 to 40 square metres.

The use of fluorescent lighting from lamps fixed to the theatre ceiling is proving satisfactory. The arrangement of the centre light is such as to allow the air to escape above it and so keep the theatre cool. A floor- or pedestal-lamp is often used for additional illumination. For contagious disease units some hospitals are using ultra-violet sterilization lamps pre-operatively in the operation theatre.

To minimize risk of anaesthetic explosions, most theatre floors are of terrazzo, with metal (not vulcanite) grids to dissipate static ceiling electricity, and noiseless, sparkless electric mercury switches are in general use. At one hospital the surgeons and theatre staff have aluminium incorporated in the soles of their shoes.

In one operating theatre an arrangement is made for students and visitors to sit in a semicircular glass enclosed dome almost directly above the operation table and a radio device enables the surgeon to carry on a conversation with those in the enclosed area outside the actual theatre.

Some hospitals maintain an individual supply of instruments for each operating theatre as against a central instrument-room. The equipment seen was first class. Locked cabinets were recessed and flush with the walls. Sponge and swab racks for easy and accurate counting were in general use. The scrub sinks, three for each pair of theatres, were of the splashless type and the flow of water was regulated by knee or foot control. An alcohol hand bath adjoined the sink in most cases. In some hospitals no sinks are used in the scrub up—merely an anti splash board supported obliquely against the wall, the water draining into a shallow gutter.

In America recovery wards or rooms are favoured. The advantages are twofold: the patient receives greater protection because the highly trained nurses are obviously better fitted—and such wards better equipped—to cope with early post-operative complications and emergencies, and the nurses in the surgical wards are relieved of the strain of major nursing at this most anxious period. The recovery ward has oxygen and every apparatus for emergency. Generally there are three or four recovery beds for each major theatre.

### The Nursing Unit

The ideal nursing unit in America is considered to comprise between 20 and 30 beds. The determining factor is the number of patients the night nurse can properly care for, the head nurse during the day hours will have as many assistants as are needed. The number of patients in such a unit is variously estimated at from 18 to 22 in single rooms, 20 to 30 in two bed rooms, and a maximum of 40 in four-bed or large rooms. The U.S. Public Health Service holds that the nursing unit should normally consist of 25 beds if mixed (that is, private, semi-private, and ward), 30 if all ward patients, and 20 if all private-room patients. A larger proportion of single rooms gives a more flexible unit, simplifies complete isolation, aids in the distribution of patients by sex, and helps to avoid the presence of conflicting personalities or noisy or obnoxious cases in the same room or wards.

Nowhere in the United States did Capt Stone find any hospital authority desiring more than six beds for a general or public ward, in Canada the number is six to eight. Two bed rooms are out of favour owing to the difficulty of selecting congenial companions, and three-bed rooms are also not liked because of the possibility of two patients combining against the third. The four-bed ward makes it easier for the sister to select psychologically compatible people. The general opinion is that beds are best placed parallel with the outer wall free on two sides and at the foot end, in such a way that the patient does not have to face the window.

The ideal bed light has not yet been evolved even in America—by 'ideal' is meant a light shaded sufficiently to be of no inconvenience to other patients in the room, and to allow maximum light for the reader in a convenient position. Some hospitals have installed a direct-call system from every bed to the nurses' station, the patient being able to talk into a bed telephone and the nurse to reply at a distance. The nurses' station is separate for each unit, in a good central position for over-all supervision, and convenient for all avenues of approach. Patients' records are generally kept in the nurses' station. In some hospitals each nursing unit has its own treatment room, containing examination table or couch, supply and instrument cupboards, instrument sterilizer, and washing facilities.

### Out-patient and Other Departments

The out-patient arrangements do not differ very much from the British pattern. The appointment system is fairly general. Departments are well marked with directing signs, and there is an information bureau to assist patients. Many hospitals have a food clinic in the out-patient department, with a view to instructing patients how best to carry out the dietary orders of the doctor.

The maternity section is separated from the other sections of the hospital. In the 15 years ending 1944, 73.1% of all births in the United States occurred in hospitals, and approximately 12% of all admissions were for confinements. It is considered that there should be one labour room for every ten patients, and one delivery-room to every 20 maternity beds. Generally the babies are viewed through glass, the visitor standing in a corridor or recess. In American hospitals admission to the nursery is forbidden to all except the nurses who scrub and gown before entering. Doctors scrub, mask and gown before making examinations.

There are many other features of American hospitals worthy of comment. Food is transported in specially designed trolleys, generally heated by electricity, with hot and cold compartments well insulated from one another. Every hospital which Capt Stone visited had a blood bank. Wiring for all x-ray equipment is separate from the general wiring system of the hospital. The use of the viewing-box with glass top light flush with the surface of a table saves much time and effort for the nurses in sorting x-ray films and putting them in their folders and containers. For hospital floors sheet linoleum bedded on linoleum felt (on a concrete base) is much used, terrazzo is also used in corridors. Rubber floors are difficult to keep clean and cork is not often seen. One feature of American hospitals is a conversation-room for confidential conversations with relatives, doctors, or ministers of religion. The patients are wheeled in and interviewed in their beds.

All hospital authorities insist that bedpans and urinals should be of stainless steel. Capt Stone was told of an innovation

which was first introduced at the Southern Hospital, Stockholm. This is a special room called the enema-room for each nursing unit. Patients are wheeled in on their beds for ordinary bowel evacuation or for enemas and washouts. The idea underlying the arrangement is that anything obnoxious should, wherever possible, be kept away from the patient's bedroom, or, in other words, his living-room.

### Courses in Hospital Administration

Eight universities in the United States and one in Canada (Toronto) have established courses in hospital administration. A division of hospital administration has been established in the school of public health of the faculty of medicine at Columbia.

The American Medical Association, through its Council of Medical Education, concerns itself with the training of medical record librarians. The training consists of not less than 50 weeks of theoretical instruction and practical hospital experience. Hospital records, by the way, are generally kept for twenty years, after which they are micro-filmed and destroyed, the micro-films take up about one tenth of the space of the records.

The certificate of approval granted by the American College of Surgeons on the recommendation of its committee on hospital standardization is regarded as an important mark of achievement by the hospitals of America and Canada. For the purpose of conferring approval the College maintains a permanent staff of field representatives who are graduates of medical schools and have had experience of clinical work and of hospital administration. This task of approval was undertaken by the College in a desire to advance the standards of surgery laid down for its Fellowship. It was found that few graduates could meet its requirements because so few hospitals were in a position to give their surgeons facilities for the proper pre-operative study of their patients. To remedy this unsatisfactory state of affairs the College prepared and published its minimum standard and introduced its certificate of approval. The standard has no legal enforcement, but the public has been educated to expect it of hospitals.

## BRITISH TUBERCULOSIS ASSOCIATION ANNUAL CONFERENCE

The annual conference of the British Tuberculosis Association was held in Belfast on June 30, July 1, and July 2 with the president Dr Frederick Haef in the chair.

Dr Bruce Clarke, director of tuberculosis services under the Northern Ireland tuberculosis authority gave an outline of the tuberculosis problem and mentioned the schemes in operation and those being planned for the control of the disease. The annual number of deaths was 1,100 and the total number of beds available was 1,200, 700 additional beds were being planned and of these 250 would be ready in about a year. The policy of the authority was to have all the beds in special chest hospitals or in units of general hospitals, so that patients would always have access to any treatment they required. The clinic and mass radiography services were to be extended, and it was hoped later to make some tuberculin surveys and statistical analyses.

Professor Arvid Wallgren (Stockholm) spoke on the "Time Table of Tuberculosis." He said that primary infection with tuberculosis was in the large majority of cases benign and without significance. In certain cases where resistance was low or other factors were involved a serious primary infection occurred, and by careful observation of the patients the various phases of the infection could be followed. The incubation period before tuberculin sensitivity developed was usually five to six weeks. Occasionally erythema nodosum, and more commonly "initial fever," marked the end of the incubation period. The second phase he considered to be the three months following the development of sensitivity. This was the period of haematogenous dissemination and was the most dangerous. Miliary spread and meningitis were most common in this phase. The third phase was from the third to the seventh month and this he called the pleurisy phase. He mentioned that it was rare for meningitis to follow pleurisy. After the seventh month the third or latent phase was entered, and during this period the lesion tended to heal, though bone lesions sometimes developed. Healing of the primary lesion was usual in the second or third

year after infection. Most of the bony lesions occurred in the first year. These phases applied to primary tuberculosis in all age groups, but age played an important part in influencing the nature of the disease. He instanced the rarity of phthisis in young children and the relative frequency of meningitis. In adolescents or young adults phthisis was common and meningitis rare, though there were many exceptions to these generalizations.

Dr Dorothy Price (Dublin) described the results of BCG vaccination of a group of infant contacts. In this group there had been no deaths from tuberculosis during a period of ten years. The vaccine was given by the intradermal method, originally in a single dose, but more recently in three doses. No adenitis occurred and only a slight local reaction. The infants were kept in hospital for six weeks before vaccination to enable those already infected to be detected. They were returned in hospital after vaccination till tuberculin sensitivity was established. In children who had had a serious primary infection with tuberculosis a marked reduction in the death rate had been obtained during the last few years by early diagnosis and prolonged bed rest. Recently, a short course of streptomycin had been tried in these cases.

#### Para-aminosalicylic Acid

Professor Jorgen Lehmann (Göteborg) described the treatment of pulmonary tuberculosis with para-aminosalicylic acid. In a large series of cases, many of them with advanced disease, improvement was noted in more than 50%. The most striking effect was an improvement in general well-being coinciding with an increase in weight, raised haemoglobin, and a fall in the blood sedimentation rate. Improvement in the radiological appearances was seen in the exudative type of disease but in the more chronic cases cavities were little affected. The treatment, however, made it possible for many of these cases to have coincident or subsequent collapse therapy. Toxic effects were not usual, though some patients had vomiting and diarrhoea. The drug was given orally in doses of 14 g daily (for an adult) divided into four or six doses. It was rapidly absorbed and excreted and a blood concentration of 3 to 6 mg per ml should be maintained. Treatment could be continued for several months, and bacterial resistance to the drug did not occur. The blood sedimentation rate was the most sensitive indicator for the management of treatment.

Dr T G Dempsey (London) gave an account of 20 cases of tuberculous empyema treated with intrapleural P.A.S. Of these 8 had broncho-pleural fistulae and were a less favourable group. Better results were obtained in the 12 non fistula cases, and a sterile fluid was achieved in 11 of them after twelve weeks' treatment. There was considerable improvement in the general condition, and some of the cases became suitable for thoracoplasty. In 6 cases the pleural space was obliterated. The speaker pointed out that procaine should not be used as a local analgesic with P.A.S. Sinuses in the chest wall healed rapidly after P.A.S. therapy was started. A small series of cases of pulmonary tuberculosis was treated with oral P.A.S. The dose given was 20-30 g per day. Results were most striking in the pneumonic and miliary cases, sputum conversion depended on cavity closure. Apart from nausea, no toxic signs were noted and the sodium salt appeared to cause even less upset.

Dr A F Foster Carter (Frimley Sanatorium) dealt with the segments of the lungs. He described their anatomical formation and their importance in disease of the lung. Tuberculous disease was not commonly confined to a segment of the lung. Other segments nearly always showed infiltration. If the area involved was segmental in distribution in a proved case of tuberculosis, tuberculous bronchitis with stenosis should be suspected. Segmental lesions occurred in primary tuberculosis, as for example in epituberculosis.

Dr Dillwyn Thomas (Sully Hospital) described a method of treatment of cavities by antipostural drainage. If the cavity were prevented from emptying in many cases it would not be visible after one or two months. Immobilization of the patient in a suitable position was essential and strict and constant nursing care was needed. Thoracoplasty was done on some of the patients after a period of immobilization.

Mr J H Carver (London) spoke on silent renal tuberculosis. He described a group of cases in which the usual symptoms of

renal tuberculosis were absent. The condition was due to occlusion of the ureter so that the bladder remained unaffected and the urine normal. The kidney might become greatly enlarged and the symptoms might suggest gastric or colonic disease. The diagnosis was made by intravenous pyelography, and the treatment was nephrectomy. Tuberculosis was present elsewhere in the body in almost all these cases.

#### Thoracoplasty

Dr Johann Gravesen (Copenhagen) described the operation of combined apical thoracoplasty with extrapleural pneumo-oleothorax, which he had used for several years. He emphasized the need for conservation of healthy lung tissue. The apicolysis introduced by Semb had been a great advance but sometimes the mobilized apex expanded again and cavities reopened. To prevent this the speaker had performed a very limited thoracoplasty with an extrapleural pneumo- or oleothorax. Extrapleural pneumothorax was dangerous where cavities were superficial, and in these cases the mobilization was done extrafascially. Very careful haemostasis of the wound space was needed and clot formation must be prevented. The space was first filled with air and after two or three weeks with oil.

Dr Joseph Smart (London) spoke of the dyspnoea which followed thoracoplasty, operations when pulmonary efficiency was impaired. Pulmonary function was difficult to assess accurately. Bronchspirometry measured the function of each lung separately and therefore had certain advantages, but it had the disadvantage that the patient must be at rest during the test and was breathing under difficulties. A more accurate assessment could be made by combining the exercise tolerance test with bronchspirometry, particularly in emphysematous patients. Marked impairment of function of one lung could be caused by obliteration of the pleural space and also by phrenic nerve interruption. In certain cases there was less impairment of function after thoracoplasty than after artificial pneumothorax. The pneumonic type of disease, superficial cavities and endotracheal tuberculosis were all contraindications to artificial pneumothorax, and treatment by primary thoracoplasty was preferable when these conditions were present.

Mr W P Cleland (London) in a paper on primary thoracoplasty emphasized the contraindications to A.P. mentioned by Dr Smart. He deprecated attempts at adhesion section in cases with "ballooned" cavities and advised thoracoplasty instead. Certain types of disease needed the maintenance of a permanent collapse and for these also thoracoplasty was indicated. The age and occupation of the patient must be considered. Very good results had been obtained in endobronchial tuberculosis with streptomycin treatment. Stenosis of the bronchus sometimes made it necessary to perform a lobectomy.

Dr James Deeny (Dublin) described his personal experience of the epidemiology of tuberculosis in two medium sized towns in Northern Ireland over a period of twenty-five years. He showed how many minor and severe epidemics developed from single cases in small areas of these towns. Ten or eleven deaths in five years were traced to a single focus. The effects of bad housing and poverty were variable. Spread of infection by direct contact was particularly dangerous to adolescents.

Dr J E Wolf (Dinos) discussed the treatment of pulmonary tuberculosis with streptomycin. He had treated 96 cases in the past three years. The results had been most favourable in the more acute forms of the disease, particularly the miliary and bronchopneumonic forms. The results in the chronic fibroid cases were less good but some improvement was effected. Doses were 1 g or less per day, and continuous treatment for three months at least was to be preferred to intermittent administration of the drug. Laryngeal tracheobronchial, and enteric forms of the disease were greatly benefited by streptomycin. Resistance developed in some of the infecting organisms, and a second or third course of treatment was less effective than the first. Treatment after such resistance had developed was harmful in some patients. Toxic effects were not common. Vestibular disturbance cleared up when the treatment was discontinued. Another toxic manifestation noticed was loss of memory for recent events, but this also cleared up after a few weeks' rest from treatment. The toxic effects he believed were due to impurities, and he had found that changing from the preparation of one manufacturer to that of another

relieved the toxic symptoms. He spoke of the diminution of toxæmia shown by all the patients treated, but was emphatic that early cases who were doing well should not be given streptomycin. The drug was most valuable in certain forms of the disease, but the standard treatment by rest and collapse therapy must not be abandoned.

Dr Johannes Holm (Copenhagen) was unfortunately unable to attend to read his paper on "refined methods of search for tubercle bacilli."

## THE NATIONAL HEALTH SERVICE AND THE DEAF

### Mr Bevan on the National Hearing-aid

The annual general meeting of the National Institute for the Deaf, which was held in London under the chairmanship of the Duke of Montrose on July 7, was addressed by the Minister of Health.

In the course of his remarks Mr Aneurin Bevan said that not until now had the deaf had statutory recognition. He believed that the word "deaf" had never appeared in a British statute before the National Health Service Act. The local authorities were responsible for looking after handicapped persons, including, of course, the deaf and dumb. It was decided when the scheme was framed that the care of handicapped persons should reside with the local authority because the service was a personal one, varying in its demands from place to place, and a national scheme would not be sufficiently flexible and adaptable for the purpose. It would be his task to see that the local authorities did their job. It was intended that the widest possible interpretation would be given to the word "workshop," for example, in the rehabilitation proposals, in order to retain in the general community those suffering from this and other handicaps.

The hearing-aid illustrated an aspect of the service to which too little attention was apt to be paid. What the new Act did was to establish people's rights or entitlement. The coming into existence of the service must depend upon the resources available, and recently the production of the hearing-aid had lagged behind expectation. A few snags had been discovered, and they had had to wait until certain technical difficulties had been overcome. The production of the aid had depended upon various techniques, some of which were developed and perfected during the war, and now a sensitive mechanism had been provided which he hoped would be of great assistance to the hard-of-hearing. Certain criticisms had been made, chiefly that the aid was not handsome in appearance. But the important thing was its efficiency, and at the same time the question of cost could not be ignored. The batteries were large, so that the instrument tended to be heavy, but if smaller batteries had been put in they would have required more frequent renewal, and therefore would have been more expensive. In connexion with this problem of the deaf they had to bear in mind that hundreds and thousands of people who had been living in solitude would be brought again into social intercourse and made not only happier and more contented but enabled to do useful work. He also looked forward to the development of research to find out more about the causes of deafness and how they could be forestalled.

At the same meeting the Chairman of the National Institute, Mr R. Scott Stevenson, said that the Institute had sought for years to have a hearing-aid brought within the range of poor people in this country. The new Government hearing-aid was an excellent job. It was the nearest approach possible to a universal aid, and for the kind of deafness that could be helped by a hearing-aid it was as good as could be got. It was a mistake to emphasize smallness of size in a hearing-aid; efficiency was wanted, not prettiness. There was, of course, a psychological element in the choice of a hearing-aid. In a recent visit to three or four rehabilitation centres in the United States he had found the central individual to be, not an otologist, nor an educationist, but a psychologist. In America great stress was laid on auditory training, and in this country the fullest benefit would not be got out of the Government hearing-aid unless it was combined with a period of training.

Lord Leverhulme said that it was estimated that 150,000 people were eligible for hearing aids. It should be remem-

bered that the provision of the aid would benefit not only those with impaired hearing but those with normal hearing also, making possible or easier the give-and-take of ordinary business and social intercourse.

The annual report of the Institute, which was adopted at the meeting, described a volume of useful and varied work done on a wholly insufficient income of about £6,500.

### A New Sound-reinforcement System

The hall of the National Institute for the Deaf, at 105, Gower Street, has been equipped with a new sound-reinforcement system—a system designed to give the most powerful and flexible aid to gatherings of the hard-of-hearing. The system embodies, among other technical contrivances, three microphones, and as many individual headphones and bone-conduction receivers as there are people in the audience requiring them. A wide range of frequency response is provided and flexible tone control arrangements permit of amplification of the particular frequencies needed for different kinds of deafness. At a demonstration the value of the installation was tested for ordinary speech and discussion and general conversation or "committee talk", to the normal hearing person the amplification, though too loud for comfort, in no way distorted the sound, and the many deaf people who tested it expressed themselves delighted with the result. A feature of the system is a roving microphone which enables the audience to participate in any discussion. It is claimed that the system, the installation of which has cost the Institute about £500, makes this small hall—the Leo Bonn Memorial Hall—the most useful and up to date meeting place for the hard-of-hearing anywhere in this country.

## MATERNITY AND CHILD WELFARE

### Encouraging Statistics

The annual conference arranged by the National Association of Maternity and Child Welfare Centres and for the Prevention of Infant Mortality was held recently in London, when the general theme was the State and family life. Dr Jane Turnbull, opening the conference as chairman of the Association remarked on the general feeling that notwithstanding the new social legislation voluntary work had still an important part to play. It was an encouraging indication to that effect that out of 145 county and county borough councils just over half were affiliated to the Association and 28 of them had joined since the passing of the National Health Service Act.

The Minister of Health, the Rt Hon Aneurin Bevan, who was president of the conference, gave an address in which he said again, as he has often done in recent utterances, that trouble was to be expected once the National Health Service Act was hunched. For some years it would not be possible to say that the Service had reached maturity. It must always appear to be inadequate. Although he was more conscious than most people of what was lacking on July 5 he believed the Service was starting with almost universal good will and before many years were over we should look back with pride upon what had been accomplished.

In the field of public health, said Mr Bevan, contributions were made from a thousand different sources and each in itself tended to be regarded as comparatively unimportant, yet in their sum they produced the progressive improvement in vital statistics which was now being witnessed and improvements in environmental health generally. The latest statistics showed another decline in the infant mortality rate—41 per thousand live births in 1947, as compared with 43 in 1946. The stillbirth rate in 1947 was 24 per thousand, as compared with 27 the previous year, and the maternal mortality rate 1.17, as compared with 1.43. All these statistics, including the birth rate, which showed an increase, proved that the sap of vitality was flowing freely in the British oak.

In addition to the refurbishing of the health organization a great deal of interesting legislation had been put through Parliament. One measure now passing through the Lords was the Dry Nurseries and Child-minders Bill. Good as this legislation was, it must never be forgotten that communal care for the child could not replace parental care. He had been a little afraid lest so much emphasis be laid upon collective activities

that the primary thing, parental relationship, might be forgotten. That was why he had attached so much importance to good housing.

Finally Mr Bevan spoke of the need for maintaining voluntary organizations. The intervention of the State into the world of hospitals and social services was not for the purpose of destroying the spirit of voluntary organization but of emancipating it from the necessity for spending so much time in the mere collection of money. In the National Health Service Act the skeleton was State organization, but the flesh was voluntary effort.

#### A Charter for Children

The conference discussed the National Health Service Act as it affected young children, environmental factors in the life of the child, and the effect of the Children Bill. In an exposition of this latest "Children's Charter" Mr John Ross, Assistant Under-Secretary of State in charge of the Children's Department, Home Office, said that local authorities had a duty to receive into their care any child in need in their area, they were enabled to make any reasonable provision for that child, including further education up to university standard to the age of 21 and beyond, they were enabled to use voluntary homes for the accommodation of children, they would have some responsibility for the care of children in voluntary homes, and by their training schemes, administered under direct control of the Secretary of State with the immediate help of local authorities throughout the country, it was hoped to provide staff who would be able to care for these children in an adequate, sympathetic, and affectionate way.

Mr John Edwards, M.P., Parliamentary Secretary, Ministry of Health, said that the smaller local authorities, although they would no longer have the responsibility that they had in the past in regard to maternity and child welfare, must not think that there was no longer a place for them in the Service. Some of the larger authorities would not be able to do this work properly unless they had the day-to-day help of the smaller authorities.

## COUNTY BOROUGH MEDICAL OFFICERS

### Annual Meeting

The annual meeting and conference of the County Borough Medical Officers of Health Group of the Society of Medical Officers of Health was held at the Aberdare Hall Cathays Park, Cardiff, from Friday, July 2, until Monday July 5. By invitation of the Group's president Dr J Greenwood Wilson, the medical officer of health for Cardiff some fifty members of the Group attended and enjoyed a varied programme. The first event was the inaugural dinner on Friday evening. The president welcomed the guests, who included the Lord Mayor of Cardiff (Alderman R G Robinson J.P.), Sir Frederick Rees (Principal of the University College of South Wales and Monmouthshire), Professor R M F Picken (Provost of the Welsh National School of Medicine), Dr Arthur Massey (Chief Medical Officer, Ministry of National Insurance), Dr A R Culley (Principal Medical Officer of the Welsh Board of Health), and Dr Trevor Jones (Senior Administrative Medical Officer of the Welsh Regional Hospital Board). The company heard some excellent speeches in reply from the Lord Mayor, Sir Frederick Rees, and Professor Picken. After dinner there followed the annual meeting of the Group and a discussion opened by Dr E K Macdonald (M.O.H., Leicester), who took as the title of his paper "The Fragments that Remain".

On the Saturday morning many members of the Group took the opportunity of visiting coal mines in the Merthyr Valley and seeing the work which was being done on the control of dust. They were entertained to luncheon at the City Hall by the Lord Mayor and returned to Llandough Hospital to hear an address by Dr Charles Fletcher, director of the Medical Research Council's Pneumoconiosis Research Unit.

At the Temple of Peace on Sunday morning, July 4, Sir Frederick Rees gave an address on post-war planning in Wales and briefly reviewed the considerations which had been taken into account by the Boundary Commissioners. Later that morning the Group heard a description of the Cardiff scheme for the follow-up of ex-hospital patients suffering from such conditions as diabetes, asthma, and peptic ulcer. The speakers were Dr D A Williams, Mr D B E Foster and the health visitor,

Miss Mary Davies. In the afternoon the party paid a visit to the Welsh National Museum, through which they were conducted by Dr North, director of the Geological Section. After tea the Group discussed medico-political matters, and after dinner they again met to hear an interesting paper on the regional hospital board and the medical officer of health by Dr W G Patterson, senior administrative medical officer of No 1 (Newcastle-upon-Tyne) Region. The discussion on this paper continued until a fairly late hour. The meeting concluded with a vote of thanks to the president for his arrangements, and to all those who had helped, including a number of medical students who had acted as stewards at the Aberdare Hall for the three days.

## REPORT OF SIMS COMMONWEALTH PROFESSOR

### Australasian Tour of Sir Hugh Cairns

Sir Hugh Cairns, the first Sims Commonwealth Professor to be appointed, travelled to Australia in December, 1947, and after a short visit there spent a month in New Zealand and then two months in Australia. He has now presented his report.\* He lectured on the work done by himself and his colleagues at Oxford, the titles of his lectures including "Blunt Head Injuries and Their Effects," "The Late Results of Gunshot Wounds of the Head," and "The Treatment of Tuberculous Meningitis by Streptomycin." He also delivered the Annual Syme Oration of the Royal Australasian College of Surgeons and the Lister Oration of the South Australia Branch of the B.M.A. In the second half of the tour he gave a number of clinical demonstrations for students or house men which were followed by general discussion, and he found that it was an excellent way of meeting all the clinical members of the hospital. At Adelaide and Sydney he discussed methods of clinical teaching with the honorary staffs of teaching hospitals, and in Adelaide answered questions from a number of young graduates about work in Britain.

He comments in his report on the general dissatisfaction in Australia and New Zealand on the number of postgraduate surgical examinations that are commonly taken. Most of them take the primary and final F.R.C.S. the final F.R.A.C.S. and the primary and final M.S. Since these examinations are very similar many people believe that young men are wasting valuable time "pot hunting." It is thought that when young surgeons come to Britain they should spend their time working with British surgeons or in research rather than in attending classes for the primary and final F.R.C.S. Australasian surgeons value their fellowships of the English College and their connexions with it and the R.A.C.S. is therefore considering having its own primary examination (there is none at present the primary M.S. or F.R.C.S. being accepted), it may then ask the English College to agree to reciprocity between the two primary examinations. Alternatively, the R.A.C.S. may ask for a combined primary F.R.C.S. and F.R.A.C.S. to be held annually in Australia. In any case they do not want to discourage men from taking the English examination.

Sir Hugh Cairns points out that there are departments in Australia and New Zealand where work of the first order is carried out. They are splendidly equipped and accustomed to training young men of outstanding ability, but with few exceptions there are no clinical departments with facilities for training postgraduate students. He suggests therefore that postgraduate medical fellowships might be established for British students to work in suitable departments in Australia. Ultimately there might be free exchange of teachers and research workers between all parts of the British Commonwealth. These fellowships should be for training in research and technical methods and be tenable for two years the fellows holding permanent appointments in Britain from which they could be seconded.

Apparently the title "Commonwealth Travelling Professor" misled many people in Australia into thinking that it signified a professor who was travelling around the Commonwealth of Australia. To avoid ambiguity Sir Hugh Cairns suggests that it might be changed to "Sims British Commonwealth Travelling Professor" if the trust deed permits.

\*Report to the Presidents of the Royal College of Physicians of London, the Royal College of Surgeons of England and the Royal College of Physicians and Royal College of Surgeons of Australasia.

ONE HUNDRED AND SIXTEENTH  
ANNUAL MEETING  
of the  
**British Medical Association**  
HELD AT CAMBRIDGE, JUNE, 1948

THE SECTIONS  
SUMMARY OF PROCEEDINGS

*In subsequent issues there will be printed in the BRITISH MEDICAL JOURNAL a few of the opening papers read at the Scientific Sections. All the papers will be published in full in a separate volume of Proceedings. The reports of the discussions concluded from last week (p. 104), are intended to give members who were not present a general idea of the proceedings.*

SECTION OF OTO-RHINO LARYNGOLOGY

Wednesday, June 30

The Sphenoidal Sinus

With the president, Mr V E Negus, in the chair, Dr Arthur W Proetz (St Louis, Missouri) read a paper on the sphenoidal sinus. With the posterior ethmoid and sphenoid sinuses it was often a case of 'out of sight out of mind'. Inferences drawn from examination of the anterior sinuses were not necessarily correct. In contact with this sphenoid sinus were thirteen important structures separated only by the thinnest bone, and sometimes even that was absent. The sphenoidal face and ostium were out of the line of inspired air, so there was no tendency to drying, except in atrophic conditions. Air exchange through the ostium was negligible, so that glands were relatively sparse. Sagittal section showed that the lining mucosa, very thin and adherent, merged with the thicker and looser nasal mucosa at the very rim of the ostium. Inflammatory blocking was therefore due solely to the nasal mucosa and could be relieved by shrinking the nasal mucosa outside the sinus. There was practically no tendency to polyposis, but an obliterative swelling did occasionally occur in allergy. Mucosal changes in chronic infections were reversible for much longer than was generally supposed. Jonathan Wright pointed this out in 1914, and showed that cilia persisted in a surprising manner.

In conservative treatment Dr Proetz favoured mild vasoconstrictors, such as 'turamine' or 0.25% ephedrine, introduced by displacement. In operating, the ostium must be carefully preserved, as it was the point to which all ciliary streams converged. A new slit-like ostium should be medial to the old one. He now treated conservatively two-thirds of the patients on whom he would originally have operated, and found he got better results.

Mr T C W Capps (London) dwelt on the clinical aspect. He said we tended to conservatism in this country. The sphenoid was well protected from air-borne and fluid borne infections and was therefore the least often infected of all the nasal sinuses. He emphasized the aid given by good radiographs in making a diagnosis of sphenoiditis. In twenty-five years experience he had had only two cases of acute sphenoiditis both treated successfully by immediate drainage. In chronic infections only the ethmoid sinuses need be drained. In his experience there was no direct connexion between sphenoiditis and retrobulbar neuritis. In treating malignant disease affecting this sinus diathermy plus irradiation gave the best results. In conservative treatment in children he preferred postural instillation of ephedrine to actual displacement.

The president, Mr Negus, congratulated Dr Proetz on his masterly paper. He felt that the sphenoid should not be regarded as a separate entity, but as one of the group of posterior ethmoids. He would like to know what was the relation

if any, of allergic swelling of the lining to migraine and of infection to mental disorders.

Mr A S H Walford (Cambridge) asked Dr Proetz if it was permissible to probe the ostium, as owing to asymmetry in sinus development, the new ostium might be made into the wrong side. Mr J C Hogg (London) had no experience of primary acute sphenoiditis but had opened many sphenoids when treating chronic pansinusitis. It was often easy to pass a cannula into the sphenoid without disturbing the middle turbinate.

Mr G H Bateman (London) was struck by the rarity in his experience of isolated sphenoidal sinusitis. Mr Donald Watson (Bradford) had seen very few cases in Edinburgh, as had his old teacher, Mr J S Fraser. He had seen cases of mental derangement cured by sphenoid drainage. Displacement and menthol snuff, had given excellent results in children.

Mr T C Graves (Birmingham) contended that there was a possible connexion between sphenoiditis and insanity. He stressed the importance of the sympathetic chain, and said that this might influence the cerebral vessels, and so the mental state. He described several cases showing dramatic improvement after sphenoid drainage. Mr J H Otty (Aberdeen) was impressed by the rarity of isolated sphenoiditis. He himself had seen only two cases. Dr J W D Bull (London) described the radiological findings in two cases, one a mucocele of the sphenoid, the other a meningioma of the anterior clinoid process.

In reply Dr Proetz agreed that it was necessary to remove the middle turbinate in fulminating cases, but in chronic cases the turbinate should be preserved. He warned against the use of cocaine and adrenaline in treatment as they paralysed cilia in a matter of seconds. There was no objection to probing the ostium, nor to enlarging the latter, provided the entire sphenoidal face was not removed. He doubted if migraine was ever caused by allergic swelling of the sphenoid lining and said he had no experience of mental cases though he was much impressed by Dr Pickworth's specimens. Radiologists should be encouraged to work with radio-opaque substances and should always use standard positions of the head.

Mr Capps replying said that by this discussion much of the aura of mystery by which the sphenoid had been surrounded had been dissipated. When he had used cocaine in treatment it had been only a 1% solution. In very acute cases one should use common sense in deciding the type of operation to employ, and in chronic cases all conservative measures should be tried first.

Poliovirus and Tonsillectomy

With the president Mr V E Negus again in the chair for the afternoon session Dr Allan M McFarlan (Cambridge) opened a discussion on poliomyelitis and tonsillectomy. He recounted the history of five children in one family who developed bulbar paralysis nine to fourteen days after tonsillectomy; three of them died. Many workers had noted a tendency for the bulbar type of paralysis to develop within thirty days of operation. Experiments on monkeys had shown that injection of virus into the tonsil region produced poliomyelitis but spraying virus on the raw surface following tonsillectomy was ineffective. In man the pharynx was a favourite portal of entry. Absence of tonsils appeared to predispose towards the bulbar rather than the spinal type of paralysis. He admitted the risk was very small but it was of course, greater during epidemics. Symptomless virus infections were common, and there was no easy method of demonstrating them. Therefore the only safeguard was to avoid operations on the tonsils during an epidemic. He did not regard the risk as a contraindication to tonsillectomy in normal times.

Dr J Alison Glover (London) compared the risks of tonsillectomy during epidemics with those of postponing the operation and suggested that the former was the greater risk. We should not know until late August or September if we were to have another epidemic this year. The virus was probably as widespread among the population as *Streptococcus pyogenes*. He quoted many authorities to show that the risk of bulbar paralysis was much greater in tonsillectomized patients and he contended that postponement of the operation last year had not caused any increase in respiratory tract infections.

Mr Geoffrey H Bateman (London) said that clinicians had refrained from operation during epidemics mainly because of

publicity But the risk was extremely small, even at the height of the epidemic The effect of the four months break in operating in 1947 had been to add enormously to the waiting list He thought parents were better judges than Dr Glover of the harm caused to their children by such postponements Surgeons would still stop operating during an epidemic, but he would still do so in urgent cases particularly if there had been no immediate contact with proven cases, and if the child could be nursed in a cubicle

The president Mr Negus, thought Dr Glover was wrong in minimizing the ill effects of postponing operation, and that his figures applied to notifiable diseases only and not to minor ailments

Mr Donald Watson (Bradford) thought the chance of an epidemic this year was small Operations for tonsils and adenoids were undertaken on the poorer type of children, in whom poliomyelitis would in any case be more prone to develop He did not believe that there was no harm caused by postponing operation

Mr F C W Capps asked why this operation was singled out Were other operations on the head and neck, or even abdominal operations, to be postponed? Could carriers be recognized by an easy test, and was segregation likely to help? If the Ministry of Health advised when operations should be stopped they should also say when to start again

Major-General E A Noyes (US Army) said their practice during epidemics was to stop tonsillectomy operations on children unless there were overriding considerations Mr J F Lipsecomb had seen many cases of poliomyelitis in Australia, where epidemics were prevalent There operations were put off as soon as the figures for poliomyelitis began to rise Poliomyelitis was no respecter of social grades There was the same incidence among children carefully isolated by their parents as among the poorer ones who played together in the streets Mr J C Hogg asked if dental extractions carried any risks

In reply Dr McFarlan said that operations other than tonsillectomy appeared to have no bearing on the incidence of paralysis There were contradictory statements about dental extractions He thought it wise to isolate operation patients on general epidemiological grounds

Dr Alison Glover quoted an instance in which fatal bulbar paralysis developed after dental extractions He agreed that cubicles were most desirable for tonsil cases but thought that this measure would not prevent poliomyelitis from developing in cases in which there was a latent infection

## SECTIONS OF MEDICINE AND SURGERY

Thursday July 1

### Surgery in Hypertension

With Professor John McMichael (London) in the chair Dr R H Smithwick (USA) opened a discussion on the indications for and results of surgery in hypertension and reviewed 256 cases followed for five to nine years He said that most of the patients were treated by bilateral thoracic lumbar ganglionectomy with removal of the sympathetic chain from the eighth thoracic to the first lumbar ganglia inclusive and of the splanchnic nerves arising from that segment Total thoracic (T2 to L1) and total (T2 to L3) sympathectomies were reserved for patients who had angina or unusual tachycardia in addition to hypertension, in order to denervate the heart as well as the splanchnic bed The advantage of the thoracic lumbar operation was that it permitted inspection and biopsy of the kidneys and examination of the adrenals An adrenal tumour causing continuous hypertension was found in 5% of cases The operation was performed in two stages the second side ten days after the first The operative fatality rate was 2% with only a slightly higher rate in males than in females In the series 40% of the patients were males and the ages varied from under 10 years to over 60 Nearly 90% of the patients were between 20 and 49 years of age Thirty-one per cent of all patients died 5-9 years after operation The 5-9-year mortality rate was specially high in patients under 20 and over 50 years of age but the numbers in these groups were small and the figures probably not significant The mortality rate varied also with the severity of the hypertension as measured by the

diastolic pressure in recumbency, 65% of the patients with a sustained diastolic pressure of more than 140 died in the 5-9-year period The mortality rate bore a direct relation also to the state of the cardiovascular system

No patients whose hypertension had been complicated by congestive heart failure and poor renal function had survived nine years Of the patients who had had congestive heart failure or poor renal function 53% died Of those who had suffered cerebral incidents 39% died, and of patients with retinal haemorrhages and exudate and papilloedema 25-30% died The causes of death in the 80 fatal cases had been cerebral accidents (48%), cardiac complication (23%), renal failure (16%), unrelated (10%), and unknown (4%)

The effect of the operation upon the various vascular areas after 5-9 years was as follows (1) The retinal changes had been improved in 40%, unchanged in 39%, and worse in 20% (2) The cardiac function, as measured by electrocardiogram, had been better in 42%, unchanged in 49% and worse in 9% (3) The renal function had been improved in 29%, unchanged in 61%, and worse in 10%

The effect upon the diastolic pressure had been classified also A marked effect had been a fall of 20 or more to below 90, a moderate effect had been a fall of 20 or more to less than 110, a slight effect had been a fall of 10-19 to below 110 In the first five-year period after operation there had been a marked fall in diastolic pressure in 35%, a moderate fall in 29% a slight fall in 20% no significant change in 11%, and an elevation in 5% In the 5-9 year period these figures had been 21, 13, 13, 36 and 17 respectively In other words, half the patients who seemed to be improved during the first five years after operation returned to the pre-operative level or higher in the second five years

He had attempted to assess the mortality of untreated hypertension but had met great difficulty in doing this because of the variations in age and severity of disease from series to series In a Swedish series 28% of untreated or medically treated patients had died in 4-11 years, in a Mayo clinic series 91% Dr Smithwick and Dr Paul White had compared two series treated and untreated, grouped according to fundus changes The mortality was substantially lower in all the surgically treated groups A similar benefit had been shown to be attained in the electrocardiograms

Dr Horace Evans (London) said that Dr Smithwick had given a masterly review of his considerable experience of the subject There was still a great lack of control data on which to assess the results of surgery Bright had suggested that arterial hypertension was always a result of disease of the kidneys, later Allbutt had pointed out that many cases had no evidence of kidney disease and finally Goldblatt had shown that renal ischaemia induced hypertension He thought now that there was a clinical subdivision into essential and renal hypertension In benign essential hypertension the cause of the disease was quite unpredictable and in those cases it was difficult to evaluate the results of surgery Women tolerated the disease better than men In malignant and renal hypertension the cause was more certain and that sympathectomy operations had an effect could not be doubted if the evidence of the hypertensive retinitis alone was considered

Subsidence of the eye changes after the operation was sometimes quite remarkable At the London Hospital at first only the most severe cases were operated on and it was hoped that renal changes might be reversible However it was found that a blood urea over 100 mg per 100 ml was a contraindication Cardiac asthma was also an absolute contraindication It was important that pre operation assessment should be as complete as possible and be based on data including a diagram of the eye-fields, cardioscopy and electrocardiograms and estimation of cerebrospinal fluid pressure The physician would tend to choose the patient who showed unmistakable progressive hypertensive disease with cardiac stress and even early renal damage, into which group came some cases of Bright's disease, but the surgeon would wish to operate before there was irreversible arterial change In spite of all these difficulties and although he regarded the operation as a formidable procedure he was sure it was worth attempting in younger patients where the prognosis without operation was certainly unfavourable

Mr D W C Northfield (London) analysed a series of 46 patients followed for upwards of six months In the first few

years most of the patients had had malignant hypertension, subsequently benign cases with retinal changes, cardiac disturbance, or high diastolic pressure had been more commonly submitted to operation. More recently still, operation had been afforded to patients with chronic nephritis who had a high and rising blood pressure but no renal failure. In all cases asthma was a contraindication but infarction was not. A blood urea of over 100 mg per 100 ml was held to contraindicate operation except in patients of the nephritis group.

Forty-six patients were submitted to operation, there were eight operative and ten later deaths. The results were much worse in males than in females. Though there was frequent systemic relief, the effect on the blood pressure was disappointing, and the only objective improvement was in the fundi. Fundus changes, if present, resolved in all patients surviving three months, though in two of these patients dying later the fundus changes returned before death.

Dr Rae Gilchrist (Edinburgh) said hypertension was the greatest medical problem of the day, being four times more common than cancer. He reviewed a group of 80 cases treated by medical means and followed up to five years and compared them with 42 patients treated surgically and followed for 8½ years. They were compared symptomatically and by repeated observations of the diastolic blood pressure, and by both methods the progress of the surgical cases was the more favourable. People with a diastolic pressure over 120 were not greatly influenced, and it was in the lower ranges that the very good results were obtained. He also spoke of a group of 30 cases of malignant hypertension followed for a period of two years. Twenty who had not been operated on were all dead, whereas of 10 treated by sympathectomy eight were alive, and one man who four years before had had papilloedema and could not work was now well and working and had married and had a son.

Dr William Evans (London) thought it important to define hypertension, and suggested that the systolic blood pressure should be over 180 or the diastolic over 110, taken on at least three occasions. He also thought that before a patient had the operation the electrocardiograph should show a low T wave or inversion of the T wave, with RT depression in leads I and CR7. There was a great deal of invalidism caused by people being told they had hypertension which did not come up to these criteria.

Mr F E Stock (Liverpool) said that the only hypertensive patients treated by splanchnicectomy in the surgical professional unit at Liverpool who showed permanent improvement were those whose hypertension appeared to have originated in pre-eclampsia. The blood pressure in pre-eclamptics had been found to fall sharply after splanchnic procaine block, but it had not been found possible to effect a permanent reduction by alcohol or "proctocaine" block. Tetraethyl ammonium bromide given intravenously had had the same vasodilator effect as procaine block, but repeated intramuscular injections had been ineffective. Splanchnicectomy therefore seemed justifiable in patients with hypertension, particularly if performed in the second trimester, since post-operative miscarriage seemed a lesser risk than spontaneous miscarriage if the disease was allowed to proceed. Splanchnicectomy seemed specially justifiable in young female hypertensives, even in the absence of symptoms, with the hope of permitting pregnancy to go normally to full term.

Mr A Dickson Wright (London) advocated extensive bilateral sympathectomy by the transpleural route.

Dr Smithwick in reply repeated his conviction that more benefit was obtained by a thoracic lumbar sympathectomy (T8 to L1) than by a more extensive operation. A lower dissection was apt to be followed by severe postural hypotension and tachycardia. The lumbar chain was removed only in a few patients who had an unusual fall in the diastolic pressure in recumbency. Malignant hypertension even, in males though not in females was sometimes associated with a return to a normal diastolic reading on recumbency. Total thoracic sympathectomy was reserved for hypertensives with tachycardia, but even in these it was unnecessary to dissect higher than T2 for a denervation of the heart. Three patients submitted to total sympathectomy had been badly incapacitated for years by postural hypotension.

To prevent cerebral and cardiac complications of operation he emphasized the importance of replacing the blood lost in mediastinal haematomas and pleural exudates, to determine this loss a haematocrit reading on the third day was invaluable. In hypertensive patients the presence of a pheochromocytoma of the adrenal was sometimes suggested even before operation by (1) severe postural hypotonia (as great almost as it usually is after operation), (2) tachycardia, (3) a basal metabolic rate of more than +20%, (4) unusual twitching, (5) hyperthermia or episodic pyrexia, and (6) pronounced response to the new adrenalytic agents—D.H.K. and benzodioxane, for example—which afforded a safer index of hyperadrenalinism than histamine injection did.

Dr Horace Evans in reply said that Dr Smithwick's reference to suprarenal tumours emphasized the need for accurate clinical assessment. He felt that Dr William Evans's figures were too high and that he would not like to have a blood pressure of 180/110. He thought that the results of sympathectomy on patients whose hypertension developed during pregnancy were dramatic.

### Macrocytic Anaemias

With Dr Branford Morgan (Norwich), a vice-president, in the chair Sir Lionel Whitby (Cambridge) read a communication on 'Pernicious Anaemia' from Professor George R. Minot (Boston, U.S.A.), who was to have opened the discussion but was prevented by illness. He said that the control of the hitherto fatal disease pernicious anaemia, which had been achieved in 1926 had happily abolished a dreadful urgency for discovering its cause. Soon thereafter a relationship of pernicious anaemia to defective digestion, surmised many years before by Coombe and by Austin Flint, had been established by Castle and his associates. This conception of a conditioned deficiency disease due to a specific disturbance of the gastric secretion and to defective absorption by the alimentary tract had been extended to include such macrocytic anaemias as those of sprue and of pregnancy. Recently von Bonsdorff had shown that the broad tapeworm might induce pernicious anaemia in persons already on the threshold of that disease apparently by inhibiting the scanty supply of enzyme remaining in their depleted gastric secretions. A few years ago Lucy Wills had shown that many patients with tropical macrocytic anaemia failed to respond to purified liver extracts of great potency. Because of the satisfactory response of these patients to relatively crude liver extracts it had then become clear that at least two substances active in human nutritional macrocytic anaemias, including pernicious anaemia, were present in mammalian liver.

The failure of early workers to isolate the active principle of liver had remained for twenty years a tantalizing challenge. Then quite unexpectedly a growth factor for the *Lactobacillus casei* synthesized by Angier and his colleagues, had been discovered by Spies and his associates to be an active haematopoietic substance in pernicious and related macrocytic anaemias. Surprisingly enough, this substance, pteroylglutamic acid, was virtually lacking in purified effective preparations of liver extract, and to date, despite the acquisition of much knowledge of its natural occurrence in conjugated forms in food, the relationship between their precursors and the active principle of liver extract and pteroylglutamic acid had not been elucidated.

Guided by the discovery of Shorr that *Lactobacillus lactis* *Dorner* required a growth factor present in commercial liver extracts, Rickes and his associates had recently announced the isolation from liver of a substance crystallizing as small red needles and had designated it vitamin B<sub>12</sub>. That material, according to clinical tests conducted by West, had been found to be haematopoietically active in pernicious anaemia in a single intramuscular injection of as little as 3 µg. Because of its extraordinary potency it could scarcely be doubted that that substance was in fact the active principle of liver effective in pernicious anaemia.

The paradox of the increased output of bile pigment despite convincing evidence of partial-maturation arrest of delivery of red cells to the circulation was well known. By feeding glycine containing isotopic nitrogen to a patient with pernicious

anaemia London and his associates had shown that in the first week of the observation about 50% of the isotopic nitrogen absorbed appeared in the stercobilin of the faeces. Because during this period few if any of the newly formed red cells of the peripheral blood containing isotopic nitrogen in their haemoglobin had been destroyed, those new facts were satisfactorily consistent with Whipple's surmise of a quarter-century ago that in pernicious anaemia stercobilin might be derived to a considerable extent from haemoglobin precursors before their incorporation into circulating red cells.

Sir Lionel Whitby then opened the discussion with a paper on 'The Modern Management of Macrocytic Anaemias'. The diagnosis of macrocytic anaemia was made by the integration of the laboratory work of the haematologist with clinical observation. Megalocytic anaemia arose from a megaloblastic erythropoiesis in the bone marrow, but it was not the only cause of macrocytosis. The methods of assessing macrocytosis were (1) colour index (but a colour index of less than 1 did not mean there was no macrocytosis), (2) haematometry, which was unreliable when there was much anisocytosis, (3) the look of the film, which was only of value to those with great experience, (4) the Price-Jones procedure, which was an academic labour, and (5) undoubtedly the best method, the volume determination by Wintrobe tube. The proof that a megaloblastic marrow was present could be obtained by sternal puncture.

Macrocytic normoblastic anaemias occurred after acute blood loss, with disturbance of liver function, acute haemolytic anaemia, scurvy, myxoedema, steatorrhoea, and refractory anaemias due to toxic factors. It might also appear in primary dyscrasias such as leukaemia. In minor degrees it was present in subacute and chronic haemolytic anaemias, where a reticulocytosis in the circulating blood also occurred, and in acidosis such as that caused by renal failure.

With regard to treatment, there were available crude, purified, concentrated, and proteolysed liver extracts and folic acid (pteroylglutamic acid). Each served its own purpose. Folic acid was of use in sprue, nutritional anaemias, and anaemias of pregnancy, it also had effect in Addisonian anaemias, but large doses often precipitated neurological symptoms. Liver, on the other hand, had a well-balanced action, though the mode of action of all the preparations was not clear. Clinical experience rather than pharmacological considerations should decide which preparation was used.

Professor J. F. Wilkinson (Manchester) said that in 19 years he had treated 1,600 cases of pernicious anaemia—68 before liver had been in use, of which 59 died within one year; 441 with stomach preparations, 513 with liver preparations, and 546 with both. In this series 301 had died with the usual diseases from which people of their age group suffered, only 47 being within a year of treatment, 100 of the living were quite well over the age of 80. He stressed the importance of diagnosis, which must precede treatment. Sufficient dosage and regular blood counts were essential. It was necessary to make sure that the extract was potent, since extracts were now made from livers which had been rejected as unfit for human food. Stomach preparations were better for cases that had spinal-cord changes since they provided more of the principle and an ounce of protein as well. Folic acid had an extraordinary effect in bringing on acute cord symptoms, sometimes within 14 days. He had treated 20 patients with it, and 15 had developed these symptoms of 184 cases described in the literature; 66 had developed them. Small doses of the drug might not maintain the blood improvement.

Dr C. C. Ungley (Newcastle-upon Tyne) said that a red crystalline material isolated from liver by Lester Smith seemed identical with the vitamin B<sub>12</sub> of American workers. The isolation of this substance had involved parallel clinical tests in over 100 patients with pernicious anaemia. The intramuscular injection of single doses of 10 µg had been followed by maximal reticulocyte responses and a rapid increase of red cells. The red crystalline material itself had not been used long enough to permit assessment of its value in subacute combined degeneration. Preliminary observations had been made in cases of subacute combined degeneration using red pigmented material containing colourless impurities. The rate of improvement in four cases had paralleled that seen in patients with crude liver extracts. The molecular weight of this substance was about 1,500.

In megaloblastic anaemias other than Addisonian anaemia the material would not necessarily prove effective. Thus, in a patient with megaloblastic anaemia of pregnancy there had been no response to the equivalent of 65 µg although the patient had subsequently responded to 2.5 mg of folic acid daily. The availability of the anti-pernicious anaemia factor in a crystalline state would aid in disentangling the other haematopoietic factors present in yeast and crude liver extracts.

Dr R. R. Bomford (London) said that the macrocytic anaemias associated with hypothyroidism still caused mistakes in diagnosis and management. The uncomplicated anaemia of hypothyroidism was never severe. The cells were enlarged, but there was no anisocytosis or poikilocytosis. The yellowish tint sometimes seen in the skin and in the plasma was due to lipochromes, which were soluble in petroleum ether, and not to bilirubin, which was soluble in alcohol. Free acid might be present in the gastric juice. That anaemia responded very slowly to thyroid alone, and iron and liver were of no value. Sometimes hypothyroidism was associated with iron deficiency or with liver-factor deficiency, and in the treatment of these anaemias thyroid and iron or thyroid and liver extract, as the case might be, were necessary to produce a complete remission. When the clinical features of myxoedema were not prominent the uncomplicated anaemia of hypothyroidism might at first sight be taken for true pernicious anaemia. Mistakes could hardly occur, however, if proper investigations were made and the characteristics of the complicated anaemia of hypothyroidism noted above were kept in mind.

Professor D. F. Cappell (Glasgow) stressed the superiority of marrow section over the smear method of examining sternal puncture material.

Sir Lionel Whitby, in reply, thought that the kernel of the discussion was accurate diagnosis, and if this was not made at the outset the picture was for always obscured.

## SECTION OF SURGERY

Friday, July 2

### Carcinoma of the Breast

With the vice-president Mr P. H. R. Ghey (Cambridge), in the chair, Sir Cecil Wakley (London) opened a discussion on carcinoma of the breast. He recollected that 7,500 women died yearly in England of this disease and that the presenting symptom was usually swelling or pain. Age was important in prognosis. Modern researches had demonstrated the fallacies in the older conceptions of lymphatic drainage from the breast. There appeared to be no grounds for the opinion that extension could occur from the axilla to the neck, the supraclavicular lymph nodes were affected only by way of intercostal and internal mammary lymphatic routes. It was wrong to believe also that drainage from the inner half of the breast was to internal mammary nodes in the upper spaces only; intercostal metastases were often found as low as the sixth intercostal space. Discussing the earliest signs of breast cancer he stressed the significance of a small swelling.

He preferred deep x-ray therapy as an adjuvant of operation rather than radium application. He then described the operative details of a modified Halsted operation. The clavicular head of the pectoralis major was left intact since it afforded a screen for the axillary vein and prevented haematoma formation in the axilla. Post-operative bleeding was also reduced if the pectoralis minor was divided through its avascular tendinous insertion in the coracoid process rather than through its muscle fibres.

Nine cases of carcinoma of the male breast presented showed the retraction of the nipple which could occur in the male as in the female breast and revealed the relatively high malignancy of cancer of the breast in males. Sir Cecil Wakley concluded with a plea for standardization of x-ray therapy throughout the country. Dr Frank Ellis (London) argued against the insertion of radium needles in the axilla and intercostal spaces, and proceeded then to consider the figures presented elsewhere by Dr McWhirter. He questioned whether the Edinburgh cases treated in the second series (local mastectomy and x-rays) were quite comparable with the earlier series (radical mastectomy).

and x rays), the numbers were so much smaller in the former that certain Stage I cases may not have been referred for radiotherapy, with consequent reflection on the value of the more radical treatment. Dr Ellis then showed by his own series from Sheffield on the one hand and the London Hospital on the other how seriously different local circumstances could disturb statistical results.

Mr J B Oldham (Liverpool) urged the need for biopsy in any case of doubtful swelling in the breast of a woman over the age of 20. He had tried many methods of treatment in a long surgical career and had become confirmed in his attachment to radical mastectomy. He avoided the operation in lactating or pregnant women in the presence of lymphoedema of the arm or of a large area of skin, and in the presence of supraclavicular swelling. Relatively localized cutaneous oedema, or attachment of glands to skin, or fixation of glands, or ulceration of skin was not, if alone, a contraindication to radical operation, but the presence of any two of these made operation of doubtful value. Like Sir Cecil Wakeley, he restricted his dissection to the area below the artery and vein, since no nodes lay above them, the sole exception to this being a few lymph nodes around the thoraco acromial axis. Radiotherapy was of value as an adjunct to surgery in all cases and as an alternative to surgery in late cases but it must not replace surgery to any greater extent than this.

Mr R L Holt (Manchester) discussed the limitations of the methods of treatment now at our disposal. Little reduction of mortality had occurred since Halsted. The Manchester method of purely clinical classification had disadvantages, 40% of Stage I cases were later apportioned by the histologist to Stage II, some 30% of Stage II to Stage I. Comparison of figures from different centres was made difficult by differences in classification.

The results of radical surgery plus post-operative radiotherapy were illustrated by 640 cases. Of these 50% were alive after five years, and 42% free from recurrence. In the performance of the radical operation Mr Holt advised the use of thin skin-flaps. The results of radiotherapy alone were not so good as those of surgery. In 111 cases treated by pre-operative irradiation subsequent histological examination showed the presence of active cancer cells in the tissue removed at operation. Deep x-ray therapy could be regarded as no more than a holding method of treatment.

Recorded results of certain American centres were then discussed. Upwards of 75% of five-year cures might be expected from radical operation and post-operative radiotherapy in Stage I tumours. From the surgical point of view there were disadvantages in pre-operative irradiation, the chief of which were delayed healing, postponement of operation, and a relatively slightly increased difficulty in operative technique because of loss of elasticity in the skin. Radium was more effective than deep x-ray therapy in killing cancer cells, but more difficult to manage. In a series treated at Manchester by Keynes's radium method the results in Stage I cases were not so good as those of radical surgery, the method was used now in cases considered unsuitable for radical mastectomy. In Stage III cancer operation must be regarded as the handmaiden of surgery.

The oestrogen and androgen drugs were not in any way curative of cancer, there was no record of a cure from either. Testosterone was preferable in pre-menopausal cases, oestrogens in post-menopausal. Improvement could be expected in only 20%. At the Christie Institute Stage I cases were treated by radical amputation alone. Stage II and Stage III cases were having pre-operative irradiation, and radical amputation as soon as possible thereafter. Stage IV cases were radiotherapeutic problems, surgery being employed only as an ancillary measure. Lieut Col W L Harnett (London), statistical secretary of the British Empire Cancer Campaign, reported a survey he had performed for the BECC of 15,200 cases of cancer treated in all London hospitals, voluntary and municipal, over a period of 18 months in 1938-9. Of these, 2,129 were cases of primary cancer of the female breast, and 23 were of primary cancer of the male breast. These had now been followed up for five years. The operation mortality was 3.1%. Only 53 patients (3.9%) were untraced. The growth was confined to the breast with no involvement of lymph nodes in 22.8%, lymph nodes were involved in 21.9% there was infiltration of skin or muscle

(with or without lymph-node involvement) in 35.7%, and distant metastases or enlarged supraclavicular nodes were present in 17.1%. Seven hundred and three patients were treated by radical mastectomy alone, the operative mortality in these was 3.1% and the five-year survival rate 47.6%.

When the cases were subgrouped into stages there was a five-year survival rate of 68.2% in Stage I, 43.6% in Stage II, 59% in Stage III with lymph-node involvement, and 25.6% in Stage III without it. Radical mastectomy was combined with radiotherapy in 393 cases, only 39.9% of these survived five years. Of 133 patients treated by local mastectomy alone, the five-year survival rate was 40.6%—59.6% for Stage I and 19% for Stage III. One hundred and seventy-five patients were treated by radium, with or without surgery, and 63.4% of these survived five years.

Mr R Sampson Handley (London) described his attempt to detect early internal mammary lymph-node involvement. Internal mammary biopsy was performed in 31 cases. These lymph nodes were found to be involved in 16 cases, sometimes even from tumours in the outer half of the breast. In a proportion of these positive biopsies the axillary nodes were not invaded, and intercostal biopsy thus served to separate from cases in Stage I a few in which radical operation could not be expected to succeed.

Mr G E Moloney (Oxford) urged the need for earlier diagnosis and affirmed that any woman over the age of 30 who harboured a swelling of the breast for over a month must be regarded as suffering from carcinoma.

Mr J R A White (Birmingham) made a plea for hormone therapy. He recorded the case of a patient 34 years old who had reported last August with a four-year-old breast cancer adherent to the skin and chest wall, and with multiple skeletal metastases. Bilateral oophorectomy had been performed, and two months later she could walk again, the breast tumour had regressed, and recalcification had been obvious radiologically in the skeleton. The breast had been removed by radical mastectomy and the area treated by x-rays. Improvement had continued to date, and the affected bones were now, 10 months later, completely re-consolidated and the patient had returned to work, though of course cure could hardly be expected. Other late pre-menopausal patients had been relieved of pain immediately and completely by testosterone.

Professor Ernest Finch (Sheffield) had been distressed always by the pain and disability of late breast cancer, the treatment of cancer of the breast did not cease after operation. He had recently had experience of the complete relief of skeletal and brachial plexus pain by the operation of leucotomy.

Sir Cecil Wakeley, replying, accepted that internal mammary deposits might explain some of the five-year recurrences after the radical operation for Stage I cancer but not for all of them, many must be due to blood-borne metastases.

## COMBINED MEETING OF THE SECTIONS OF ANAESTHETICS AND OBSTETRICS AND GYNAECOLOGY

Thursday July 1

### Analgesia in Midwifery

The president of the Anaesthetics Section, Dr Z Mennell (London), took the chair and opened the proceedings by defining the scope of the discussion. It was important at the outset to define terms and to differentiate between institutional and domiciliary practice. After a plea that chloroform should not be neglected he called upon Professor W C W Nixon (London) to open the discussion.

Professor Nixon said that the ideal type of analgesic for labour had yet to be found. The method must not endanger the life of the mother or child. Asphyxia neonatorum was still too often due to the analgesic or anaesthetic used. At University College Hospital Dr Shila Ransom was in sole charge of the analgesia in the department and with a research team was investigating all the new drugs. He strongly recommended that new drugs should be tried first on human volunteers and their effect on the respiration noted before giving them to women in labour. Pethidine took first place among the drugs at present available. After a study of 500 cases it had been found that 150 mg injected intramuscularly gave relief from pain

without respiratory depression in the baby. Any increase in this dose tended to cause such depression. The use of chloral hydrate, the bromides, barbiturates, and omnopon and scopolamine was reviewed. Anoxia at birth might give rise to an impaired I.Q. later in life. The action of drugs on the uterine contractions must be considered, and there was now an apparatus which would measure the amplitude and frequency of the contractions. Finally, the better the preparation given to expectant mothers for childbirth the less analgesia would be required. Pre-natal explanation and training should be obligatory.

Dr P. J. Helliwell (London) reviewed the results of the work he had carried out with Dr. Hutton as research fellows of the Association of Anaesthetists of Great Britain and Ireland. He said that very satisfactory analgesia could be produced with nitrous oxide and oxygen and by the portable gas-and-air machine devised by Minnitt. Chloroform could not be administered by midwives, and in this respect trichlorethylene was not without danger. None of the inhalers available for the vaporization of the latter substance could really be depended upon to give a constant strength of vapour. Patients might pass into anaesthesia and must be supervised. A very efficient analgesia using a high percentage of oxygen could be achieved by the inhalation of 5% cyclopropane and oxygen. In America rectal ether took the place of gas and air in this country.

Dr A. M. Hutton (London) discussed the signs of overdosage with trichlorethylene, mentioning cardiac arrhythmia and tachypnoea. An investigation had been undertaken in sixteen hospitals throughout the country on the efficacy of trichlorethylene and its safety for domiciliary use. This investigation was undertaken under the auspices of the Royal College of Obstetricians and Gynaecologists. A total of 2,354 cases had been reviewed. All had used Freedman's inhaler, and 90% of the patients had had satisfactory analgesia. No increase in the number of cases requiring instrumental assistance had been observed, and it was clear from this survey that trichlorethylene was better than gas and air if the analgesia was started late in labour or without preliminary instruction. Trichlorethylene crossed the placental barrier, but there had not been any increased incidence of asphyxia neonatorum, except when it was used with other analgesics.

A long discussion followed. Dr G. S. W. Organe (London) pleaded that an anaesthetist should supervise the analgesia in departments of obstetrics. No baby need die from asphyxia neonatorum, since all that was needed was oxygen and artificial respiration. He deprecated the use of undiluted carbon dioxide, which was dangerous and had probably asphyxiated many newborn babies; the mixture with oxygen was extremely valuable. Dr C. G. Roworth (Swindon) stressed the importance of gaining the complete confidence of the patient. This was not always achieved in the larger clinics. Morphine should not be withheld, especially to ensure rest at night. Mr F. R. R. Martin (Bradford) liked to use chloroform with a Junker inhaler, in his hands this had always proved satisfactory, portable, and convenient.

Mr J. H. Peel (London) stated that no analgesia gave such complete freedom from pain as caudal anaesthesia. He was pleased to hear that anaesthetists no longer regarded the technique as difficult. In primigravidae its use was contraindicated because of the increased incidence of forceps deliveries, but in multiparae and for obstetrical manipulations and operative procedures it was most useful. He was sorry that this country seemed to be lagging behind America in the use of this method. Dame Louise Mellroy supported Professor Nixon in his demand that only the best anaesthetists should deal with obstetrical cases. She gave 10-15 gr (0.65-1 g) chloral each night for a week before labour, as she felt that this helped to relax the cervix. The psychological preparation of the patient was important. The most painful stage was at the end of the first stage and it was then that analgesia must be used. Dr G. G. Lennon (Oxford) read a short note from Professor Chassar Moir's department describing a new machine designed by Mr A. Warming, of Copenhagen. This machine had been in use in Denmark for years. It delivered 80% oxygen and 20% nitrous oxide. In the Radcliffe Infirmary it had been used in 60 cases with good results. Dr G. F. Rawdon Smith (Liverpool) said that women generally should be taught not to terrify intending primiparae with descriptions of their confinements.

Dr H. N. Gregg (Coventry) felt that the obstetric education of the patient should start not with her pregnancy but at puberty.

Dr H. P. L. Ozorio (Hong Kong) regarded the women of the Western world as spoilt. The Chinese mother was more phlegmatic and made a good patient. It was important to consider the psychological make-up of patients when discussing analgesia. A mother who heard her baby cry seldom had post partum haemorrhage. Dr Edith Gilchrist (London) noted a discrepancy in the findings with hysterography as between Nixon and Bourne. Unlike Professor Nixon, the latter found that nitrous oxide actually increased the uterine contractions.

## SECTION OF-OBSTETRICS AND GYNAECOLOGY

Friday, July 2

### Third Stage of Labour and its Complications

With Professor Hilda N. Lloyd (Birmingham) in the chair, Dr J. D. S. Flew (London) opened the meeting by saying that it was his desire to be provocative in his remarks and to put forward the following questions: (1) Should the obstetrician's or midwife's hand be placed on the fundus of the uterus during the third stage of labour, and, if so, how should it be placed? (2) In third stage haemorrhage should the use of ergometrine be advised, especially for midwives? (3) Was bimanual compression of the uterus possible per abdomen? (4) How long should the third stage of labour be allowed to continue in the absence of haemorrhage?

Dr Flew reviewed the physiology of the normal third stage and said that it appeared that the primary factor causing placental separation was at a maximum at the moment of expulsion of the baby's body, and that the time which lapsed before we considered the placenta ready for expulsion was concerned with the action of the secondary powers and the separation of the membranes from the uterine wall. A badly conducted third stage could cause post-partum haemorrhage, the bad conduct consisting usually in feeble attempts to express the placenta by massage and the pushing of the uterus downwards. This downward pressure of the uterus was considered to be dangerous possibly by its action of causing uterine engorgement. If the uterus was to be touched at all it should be held with a wide grip suprapubically and, if anything, pushed upwards rather than downwards. It was suggested that the midwife should not be discouraged from using ergometrine as the danger of a constriction ring was more apparent than real. Midwives in all districts should be allowed to carry ergometrine in their bags.

Bimanual compression of the uterus after removal of the placenta was possible with both hands on the abdomen, a broad suprapubic grip on the uterus was maintained while the other hand was placed on the posterior wall of the uterus per abdomen. Unless the patient was grossly fat it was surprising how efficiently the placental sinuses could be compressed by this method. In the absence of bleeding, and if the third stage of labour had been well conducted the placenta should be removed within one hour of the baby's birth. Properly conducted bimanual removal of the placenta was not a dangerous operation. Dr Flew warned against holding the baby high above the level of the mother before clamping the cord since by doing that it was possible to transfuse the placenta with baby's blood.

Professor H. L. Sheehan (Liverpool) pointed out that his remarks dealt with the failures in treatment and not the successes. The cases he mentioned were those dying following retained placenta, or as a result of post-partum haemorrhage in the fourth stage, apart from cases of ruptured uterus, serious lacerations, etc. Two thirds of these patients died from haemorrhage and shock in the first 12 hours after delivery, and the other one-third recovered temporarily but died later in the puerperium.

There were four main groups of cases of retained placenta: (1) Placenta separated completely but held *in utero* by a constricting ring—not usually a sufficiently serious condition to be a cause of death. (2) Placenta not separated though normally attached to uterus. One part, the lower, was usually separated and had caused considerable haemorrhage. There was no anatomical reason for the retention, since the remainder of the

placenta easily separated. The cause appeared to be poor retraction of the uterus. (3) Placenta morbidly adherent at one or two places, due to structural abnormality of the attachment. Usually in this type of case a piece of placenta was retained *in utero*. (4) Placenta morbidly adherent all over—placenta accreta.

There were three factors to be considered in cases of death (usually within eight hours of the birth of the baby) due to retention of the placenta—namely, blood loss, traumatic shock due to the manner of removing the placenta, and the length of the third stage of labour. Blood transfusion was of no value in cases of shock without loss of blood. Obstetric units where active interference in the third stage was the treatment enforced had been compared by Professor Sheehan with units where no interference was countenanced, and the results showed little or no difference. Most of the deaths were of patients left for three to seven hours with the placenta *in utero*.

Dr P. L. Mollison (London) discussed the rhesus factor, the importance of transfusing women with Rh negative blood and of treating immediately haemolytic disease of the newborn. It had been shown that infants born to women who had been sensitized as a result of blood transfusions were more severely affected than the average and in fact had a mortality rate of approximately 50%. When an Rh-negative woman in whose serum anti-Rh had been found went into labour it was important that facilities for treating the baby were prepared. Since a proportion of these infants were in a critical condition at the moment of birth it was a wise precaution to have ready an oxygen tent in which the infant could be placed immediately after birth.

Opening the general discussion Mr F. R. Stansfield (Ipswich) made a plea for the planned use of the abundant knowledge we already possessed. He had investigated ten deaths due to post-partum haemorrhage, and had found that in each and every case the fatal outcome was due primarily to delay. He outlined a set plan of campaign for treating such cases. Dame Louise McIlroy (London) was of the opinion that slow extraction of the baby's head (up to 20 minutes) and slow extraction of the placenta when separated were important steps in the conduct of labour. She advocated a suprapubic pad with a many-tailed binder in the treatment and prevention of post-partum haemorrhage. Mr G. G. Lennon (Oxford) illustrated important steps and dangers to be avoided in manual removal of the placenta. He stressed the necessity for getting to the fundus of the uterus as a first step in order to diagnose constricting ring, and to begin separation from above downwards so that the uterus might retract down on the sinuses opened up. Other speakers advocated early manual removal of the placenta while the woman's condition was good.

Dr Flew, in summing up, said that there had been a great measure of agreement on the necessity for using oxytocic drugs and early manual removal of the placenta in the treatment of post-partum haemorrhage.

## SECTION OF DISEASES OF THE CHEST

Thursday July 1

### Upper Respiratory Disease and Certain Lung Conditions

With the president, Dr R. R. Trail (London), in the chair, Dr W. Paton Philip (Cambridge) opened the discussion by stressing the essential unity of the upper and lower respiratory tracts in relation to diagnosis and treatment of respiratory diseases. Certain broncho-pulmonary conditions were described which coexisted with or might be ascribed as due to infections of the upper respiratory tract, including especially the paranasal sinuses. The pulmonary conditions were often transient, but were frequently recurrent unless efficient and often prolonged treatment was directed to the paranasal sinus infections. Co-existing pulmonary conditions were largely or most frequently due to lobar collapse or atelectasis, lobular collapse, broncho-pulmonary segmental collapse, or partial deflation by bronchial emboli. Examining doubtful radiological shadows in the lung they should remember that the aphorism of Twining "Think atelectasis," was sound doctrine. Radiological investigation should include the lateral and lordotic views.

The site of election was in the lower lobes and right mid-lobe, as opposed to the upper lobes. Pulmonary abscess with

"pneumonitis" in this series was conspicuous by its absence. Tuberculin testing in the case of children in the series had given consistently negative results. His study was based on personal experience extending over 25 years, and included 372 cases annually occurring among an annual average attendance of 2,375 new cases referred to an out-patient chest clinic for opinion by general practitioners, school medical officers, and ENT surgeons. Sinus infection, with resulting atelectasis, if not relieved may prove to be the forerunner of frank bronchiectasis.

Dr R. R. Trail emphasized that lung abscess was not found associated with paranasal sinus infection. Dr F. H. Young said that he found lipiodol in a paranasal sinus immediately after a bronchogram had been made. There was evidence to suggest that, as the paranasal infection might cause the lung infection, so an established lung infection might cause or prolong a paranasal infection. In reply to a question by Dr Young, Dr Paton Philip said that in routine examinations it was sufficient to x-ray the frontal sinuses and antra.

Opening a discussion on "The Present-day Treatment of Pneumonia," with Dr F. H. Young (London) in the chair, Dr Lindsey W. Batten (London) asked whether, treatment apart, lobar pneumonia was the disease it had been 30 years ago? Had it, before chemotherapy, already become, like some other acute infectious fevers, a disease of waning intensity?

Before the day of chemotherapy the problem had been not to cure a self-limited disease but to sustain the patient's resistance until he had recovered. The length of the course had been all-important, exhaustion the danger most feared. Rest, nourishment, and economy of exertion had been first objectives, and expert nursing in hospital the obvious means to their attainment. Chemotherapy, by greatly shortening the course of fever and toxæmia, had largely eliminated the danger of exhaustion in those not handicapped by age or serious incidental disability. Home, not hospital, might be the place of choice and the management of pneumonia at home thus assumed a new importance.

Many details of management were still open to discussion—e.g., temperature of room and relative importance of ventilation and warmth, the allocation of priority among sleep, food, and drugs, hot, tepid, or cold water for sponging, the patient's position in bed, the drugs for relief of pain and cough, for sleep, and as aperients, the usefulness or futility of poultices, the place of oxygen and of cardiac or respiratory stimulants in treatment. Chemotherapy was not standardized. No close agreement appeared between recent authorities on the choice or dosage of sulphonamides, the precise place of penicillin in treatment and even the method of administration had probably still to be determined. Finally, the considerable minority of pneumonias benign or virulent, untouched by chemotherapy must not be forgotten.

Dr F. H. Young produced evidence, based on the number of cases referred to a consultant, which suggested that pneumonia had begun to decrease in clinical severity before the use of sulphonamides. It appeared that one did not see now the classical type of lobar pneumonia.

Dr R. R. Trail said that any statistics of pneumonia in general practice must depend on two main factors—the prevalent infections in the doctor's area and the criteria he set up for treatment at home as against treatment in hospital. There was a definitely improved prognosis of all forms of pneumonia since the introduction of the sulphonamides, moreover, these agents were now given in most cases in the earliest possible stages, and it might well be that many of the so-called non-bacterial types were arrested developments of what would have proceeded to a full-blown pneumonia. There was also nowadays an increasing use of x-ray diagnosis. A third factor to be considered was that during the war all chest conditions in young people had a much greater chance of early admission to service hospitals. Published results on the proportion of bacterial to non-bacterial pneumonia did not help with regard to the general population. American estimates varied from 15 to 75%. Possibly the age of incidence was higher and symptoms and signs were changing somewhat—e.g., rusty sputum was said to be much less common than it had been some 10 years ago.

Dr G S Haynes (Cambridge) agreed that orange juice, glucose, and fluids were sufficient food for cases of pneumonia. Dr R G Anderson (Cheltenham) said that his impression was that, whereas empyema had been as frequent or perhaps more frequent when sulphonamides had first been used, it was now becoming rare. Could this be the result of penicillin treatment?

Dr Lindsey Batten, in summing up, said that the main difference from former times was that the present type of pneumonia did not become full-blown. Some people were more liable to repeated attacks of pneumonia than others—e.g., those with sinus infections, and others who might have low resistance in the lower air passages. The present type of disease did not progress to rusty sputum production. When he used the term pneumonitis he referred to a presumed pathological state of a portion of lung. By pneumonia he referred to a general state of illness of a patient.

## SECTION OF ORTHOPAEDICS

Thursday July 1

### Operative Treatment of Recent Fractures

With the president, Professor T P McMurray (Liverpool), in the chair, Mr Bryan McFarland (Liverpool) opened a discussion on the operative treatment of recent fractures, which he divided into three categories. First, those in which operation was *essential*, secondly, those in which it was *permissible*, and thirdly, those in which it was, to say the least, *inadvisable*. As a result of treatment the patient should be at least no worse off than if he had been left alone, and to justify open operation there must be a reasonable probability that the result would be better than if a closed method had been used. The added risk of interference must be balanced against the probable benefit either in time or in degree of relief. The separation of the three groups might vary with the skill and experience of the surgeon, but no cases should be put into the last group because of fear of the possible results in inexperienced hands. No such hands should be permitted the opportunity of prejudicing what was otherwise perfectly good practice.

Mr McFarland gave the following examples of fractures in which open operation was essential. In fracture of the lateral condyle of the tibia with separation of a large fragment which was irreducible because of interposed material operation was essential in order to restore shape, movement, and stability. Fragments from a comminuted patella must be excised and the extensor mechanism repaired, a similar repair was required in transverse fractures whatever method was used to deal with the bone. Operation was also essential in fracture-dislocation of the humeral head, fracture with rotatory displacement of the lateral humeral condyle, incarceration of a medial epicondyle within the elbow joint (but without transposition of the ulnar nerve), fracture of the olecranon, in which small fragments were excised and the larger ones fixed by a screw, and fracture of the radial head with comminution. Operation was *permissible* for fracture-dislocation of the tarsal scaphoid, grossly comminuted fracture of the os calcis, when excision of the fragments relieved the tension and partial ischaemia of the foot, unstable oblique fractures of the tibial shaft, irreducible supracondylar fracture of the femur, intertrochanteric fractures in which external fixation might be impracticable on account of the age and condition of the patient, transcervical femoral fractures, Monteggia's ulnar fracture with dislocation of the radial head, single oblique fracture of the lower third of the radius, and occasionally for fractures of both bones of the forearm. Operation should *not* be performed for comminuted fractures of the os calcis without gross displacement, Pott's fracture-dislocation, simple fracture of the tibial shaft, comminuted fracture of the tibial condyle, or for fracture of the shaft of the femur. In the latter the anatomical perfection of end-to-end alignment did not justify the risks of delayed union which plating might produce. Fracture of the carpal scaphoid did not require operation, the results had been very disappointing. It was obvious that many other common fractures such as Colles's fracture should not be operated upon. He felt that the great advantage of open operation was when one fragment was so small or so shaped that it could not be replaced or retained and it was clear that persistent displace-

ment or non-union would prejudice function to a serious extent.

Mr James Patrick (Glasgow) said that the radiographic appearances were of no importance if the clinical result was perfect, therefore he agreed that the simplest method with least risk to the patient should be adopted in almost all cases. Where open operation was necessary the introduction of ordinary steel was bad because it corroded and led to devitalization of the adjacent bone and possible later spontaneous fracture. The use of two dissimilar metals accelerated the disintegration. The metals most suitable were stainless steel or vitallium. Mid shaft fracture of the radius alone, often considered a simple problem, was an example of the need for particular care because of the possibility of late displacement and consequent derangement of the inferior radio ulnar joint. If this occurred early open fixation was required. In fracture dislocation of the upper end of the humerus he believed that open operation would be needed less often if traction was applied to the arm in 90° abduction and 40° forward flexion with the patient half supine. An incarcerated medial epicondyle could be extracted from the elbow joint without open operation by the application of faradism to the flexor muscles while the patient was anaesthetized.

Mr A L Eyre-Brook (Bristol) said the indications for operation ranged from those which were essential, as in open fractures, through less essential grades, such as fractures requiring internal fixation to obtain union, small fragments in fractures involving joints, and cases showing failure to maintain adequate reduction of two major bones in one limb. In the final group operation was *elective* as for example, when it was employed to reduce the period of immobilization. Dangers still existed in spite of penicillin. Good judgment was needed and the good surgeon would plan his treatment not only upon his own ability but also upon the circumstances in which he was working.

Col H R Sheppard, R A M C, said that because operation delayed union more prolonged immobilization was required with splints afterwards than when closed methods were used. Mr W R D Mitchell (Rugby) said that operations, if necessary, should be done within the first two or three days. Both Mr B Whitchurch Howell (London) and Mr Norman Capener (Exeter) stressed the value of operative fixation of fractures in the region of the femoral trochanters as giving an easier convalescence for the elderly patient. Mr A D Le Vray (London) describing a recent visit to Professor Kuntze's clinic, stated that 5% of the nailed cases became infected and this and the large amount of x-ray screening necessary were major drawbacks from a British point of view. Mr R W Butler (Cambridge) made a special plea for operative treatment in old people, it could at times give them freedom from irksome fixation. Mr James Russell (Glasgow) considered that Mr McFarland had presented a well-balanced statement of the operative treatment of fractures in general, and he felt that the aim must always be to attain the maximum of function with the minimum of risk.

Mr McFarland, in reply, said that, while operation would still be necessary where function would otherwise be impaired, he wished to say as emphatically as possible that wholesale operations on closed fractures were to be utterly and completely condemned.

### Treatment of Acute Haematogenous Osteomyelitis

Dr J Trueta (Oxford) said that acute haematogenous osteomyelitis was caused by pyogenic bacteria, most commonly the *Staphylococcus aureus*. The organism usually reached the bone in the blood of the nutrient artery. Thrombosis was an early phenomenon of the infection, and the extent of damage to the bone depended on the area deprived of its blood supply. This area was determined by the position in the vessel of the original focus, by the spread of the thrombosis, and later by the spread of the pus into the subperiosteal space, where by the stripping off of the periosteal vessels, the cortex was also deprived of its remaining blood supply. Modern treatment aimed at the preservation of as good a blood supply to the bone as possible and achieved it by the combination of early intensive and sufficiently prolonged penicillin treatment, early relief of the intra-osseous and subperiosteal pressures by limited conservative surgery, and correct immobilization of the affected

part Success depended on the prompt use of these three therapeutic elements, and the main prerequisite for effective treatment was early diagnosis It was necessary that every clinician and general practitioner should be aware of this urgency, since in the last resort success or failure of the treatment was determined by the time elapsing between the first symptom and the patient's arrival in the surgical ward of the hospital Multiple drill holes were made throughout the extent of the lesion into the medullary cavity Penicillin was given generally by intramuscular drip to the extent of 400,000 units in twenty-four hours for the first three days, 300,000 units on the fourth day, and 200,000 units on the fifth day and onwards, these amounts being varied according to the weight of the child It was important to have the full resources of a pathological laboratory for the isolation of the organism and for testing its sensitivity

In the subsequent discussion several speakers referred to the supposed difference in incidence as between rural and industrial populations Dr Trueta, in reply, said that it was essentially a matter of 'soap and water' Where standards of cleanliness were high the incidence of osteomyelitis was low

## SECTION OF PATHOLOGY

Thursday July 1

### Acute and Subacute Hepatitis

With Professor Dorothy Russell (London) in the chair, Professor H P Himsworth (London) opened the discussion and said that the clinical picture of acute, subacute, and chronic hepatitis (cirrhosis) did not entirely correspond to the pathological findings The clinical features of acute hepatitis resulting from acute or subacute necrosis were well recognized Subacute hepatitis was characterized by anorexia, enlarged liver and spleen, oedema of the ankles, and spider telangiectasis Jaundice might be absent throughout the illness In the plasma there was a low albumin and raised globulin content These patients went on to develop a chronic hepatitis, and cirrhosis was seen at necropsy Subacute hepatitis could be produced experimentally with typical lesions in the liver, leading to irregular scarring, among cases of normal parenchyma Although the causation of many cases was obscure the level of nutrition might determine whether an acute case would recover or go on to the subacute stage

Professor J H Dible (London) described the histological changes revealed by liver biopsy The changes were essentially the same whether the hepatitis resulted from arsenotherapy (54 cases with 2 deaths), "serum jaundice" (15 cases with 2 deaths), or acute idiopathic (catarrhal) jaundice (23 cases with no deaths) There was a disappearance of cells around the central vein, with swelling and degeneration of surviving cells, there were normal cells at the periphery of the lobule and some infiltration of the portal tracts with lymphocytes plasma cells and polymorphs The reticular pattern was well preserved, and this might play some part in regeneration Although the lobule shrank there was an apparent increase in the supporting framework due to condensation Bile could be demonstrated in the necrotic liver cells and endothelial cells and as bile thrombi in the bile canaliculi The essential lesions therefore were destruction and necrosis which followed the passage of bile into the blood stream and an obstruction by bile thrombi There was a remarkable absence of fat but glycogen was well preserved The usual result was complete cure though death might occur in severe cases, or the process might resolve, leaving a liver scarred by fibrosis In moderately severe cases young fibrous tissue might form between the bile tract and the central vein, leaving rounded islets of liver tissue with surviving cells

Dr G W M Findlay (London) spoke of the effect of malnutrition in the causation of hepatitis, first described in 1500 when Columbus's sailors returned with jaundice as a result of their appalling diet Hepatitis was common in the Tropics, particularly when a poor diet was accompanied by malarial infection Dr Findlay gave statistics showing the higher mortality from hepatitis among natives in West Africa as compared with Europeans, and suggested that this was due to the low protein diet of the natives and the high incidence of malaria He

hoped that records of all cases of hepatitis treated with casein hydrolysate would be collected, as he had seen 5 patients in coma who had recovered dramatically after intravenous casein

Dr J A R Miles (Cambridge) drew attention to the association between bacterial infection and hepatic necrosis and cirrhosis, and particularly to the adjuvant action of bacteria on the toxic effects of chloroform and phosphorus He had produced acute necrosis of the liver in rats on low protein diets, insufficient in themselves to cause necrosis, when chance infection with *Salmonella typhi-murum* had occurred Experimental lesions in rats had been produced with infective hepatitis material but had failed after 13 passages Other material, including some from icterogenic serum, had failed to produce lesions

Dr J N P Davies (Uganda) recalled the fibro-fatty liver disease seen in Africans which led to pseudo-monolobular cirrhosis Infective hepatitis and acute necrosis also occurred but led to an intermediate type of lesion similar to that described by Professor Himsworth He thought that infections and abrupt malnutritional episodes in Africans might cause these lesions when superimposed on the fibro-fatty liver changes already present He also suggested that the 'oestrinization' which commonly appeared in male Africans (gynaecomastia and feminization of the skeleton) might play a part in the high incidence of primary hepatic carcinoma in Africans, and thought that the role of the endocrines in liver disease should be studied

Dr J Gillman (South Africa) said that the genesis of cirrhosis was different in South African natives from that in India and the USA He made a plea for a world survey of cirrhosis in different groups in different states of nutrition

### Prophylaxis of Virus Infections

With Dr R I N Greaves (Cambridge) in the chair, Dr C H Andrewes (London) opened the discussion and said that vaccines made from viruses inactivated by formalin or ultraviolet light might give useful and safe protection—for example in influenza—but this protection was not of long duration Attenuated living viruses gave protection for a longer period and the 17D strain yellow-fever vaccine was an ideal vaccine with a trivial general reaction and long immunity Many viruses grown on eggs altered enough to allow of suitable prophylaxis without reaction—e.g., influenza, mumps, and measles The existence of numbers of serological strains, however complicated the task In influenza strains A and B were unrelated antigenetically and epidemiologically, A being responsible for epidemics every two to three years and B every four to six years Some success with influenza vaccines was achieved in 1943 and 1946, but they were a complete failure in the 1947 epidemic To study variations and to collect strains from all sources the World Influenza Centre had been set up at Hampstead He described the experimental production of immunity by the interference phenomenon Ferrets infected with an influenza B strain which had little effect on them were later infected with known virulent influenza A with no ill effect Later contact exposure was also without effect This might be a pointer to artificial virus immunity, as the phenomenon also occurred with serologically unrelated viruses He described the recent developments in the field of prophylaxis against mumps, measles, rubella, rabies, and the common cold The work on the common cold at the Salisbury centre had not yet reached a conclusion He described attempts at prophylaxis of the common cold with bacterial vaccines as flogging a dead horse, and thought that the volume of controlled scientific evidence available was enough to have killed the horse

Professor R Hare (London) agreed that it was still impossible to protect humans against many of the commoner virus infections The study was difficult because of the lack of susceptible animals and of the technical difficulties in the preparation of large quantities of virus vaccines even from eggs—themselves in short supply Inactivated viruses on the whole were less satisfactory than attenuated vaccines Even if they appeared to protect animals they often fail to protect humans, especially under field conditions

Professor W I B Beveridge (Cambridge) was more optimistic in his suggestion that, while immunization was judged by its poor results in the individual, herd immunity might be greatly

Dr G S Haynes (Cambridge) agreed that orange juice, glucose, and fluids were sufficient food for cases of pneumonia. Dr R G Anderson (Cheltenham) said that his impression was that where empyema had been is frequent or perhaps more frequent when sulphonamides had first been used, it was now becoming rare. Could this be the result of penicillin treatment?

Dr Lindsey Bitten, in summing up, said that the main difference from former times was that the present type of pneumonia did not become full blown. Some people were more liable to repeated attacks of pneumonia than others—e.g. those with sinus infections and others who might have low resistance in the lower air passages. The present type of disease did not progress to rusty sputum production. When he used the term pneumonia he referred to a presumed pathological state of a portion of lung. By pneumonia he referred to a general state of illness of a patient.

### Operative Treatment of Recent Fractures

With the president Professor T P McMurray (Liverpool) in the chair, Mr Bryan McIlrland (Liverpool) opened a discussion on the operative treatment of recent fractures which he divided into three categories. First those in which operation was essential, secondly those in which it was *permissible*, and thirdly those in which it was to say the least *advisable*. As a result of treatment the patient should be at least no worse off than if he had been left alone and to justify open operation there must be a reasonable probability that the result would be better than if a closed method had been used. The added risk of interference must be balanced against the probable benefit either in time or in degree of relief. The separation of the three groups might vary with the skill and experience of the surgeon but no cases should be put into the last group because of fear of the possible results in inexperienced hands. No such hands should be permitted the opportunity of prejudicing what is otherwise perfectly good practice.

Mr McIlrland gave the following examples of fractures in which open operation was essential. In fracture of the lateral condyle of the tibia with separation of a large fragment which was irreducible because of interposed material operation was essential in order to restore shape, movement and stability. Fragments from a comminuted patella must be excised and the extensor mechanism repaired. A similar repair was required in transverse fractures whatever method was used to deal with the bone. Operation was also essential in fracture dislocation of the humeral head, fracture with rotatory displacement of the lateral humeral condyle, incarceration of a medial epicondyle within the elbow joint (but without transposition of the ulnar nerve), fracture of the olecranon, in which small fragments were excised and the larger ones fixed by a screw, and fracture of the radial head with comminution. Operation was *permissible* for fracture dislocation of the distal scaphoid, grossly comminuted fracture of the os calcis when excision of the fragments relieved the tension and partial ischaemia of the foot, unstable oblique fractures of the tibia, high irreducible supracondylar fracture of the femur, intertrochanteric fractures in which external fixation might be unpracticable on account of the age and condition of the patient, transcervical femoral fractures, Monteggia's ulnar fracture with dislocation of the radial head, single oblique fracture of the lower third of the radius and occasionally for fractures of both bones of the forearm. Operation should *not* be performed for comminuted fractures of the os calcis without gross displacement, Pott's fracture dislocation, simple fracture of the tibia shaft, comminuted fracture of the tibia condyle, or for fracture of the shaft of the femur. In the latter the anatomical perfection of end to end alignment did not justify the risks of delayed union which plating might produce. Fracture of the carpal scaphoid did not require operation, the results had been very disappointing. It was obvious that many other common fractures such as Colles's fracture should not be operated upon. He felt that the great advantage of open operation was when one fragment was so small or so shaped that it could not be replaced or returned and it was clear that persistent displace-

ment or non union would prejudice function to a serious extent.

Mr James Patrick (Glasgow) said that the radiographic appearances were of no importance if the clinical result was perfect, therefore he agreed that the simplest method with least risk to the patient should be adopted in almost all cases. Where open operation was necessary the introduction of ordinary steel was bad because it corroded and led to devitalization of the adjacent bone and possible later spontaneous fracture. The use of two dissimilar metals accelerated the disintegration. The metals most suitable were stainless steel or vitallium. Mid shaft fracture of the radius alone often considered a simple problem was in example of the need for particular care because of the possibility of late displacement and consequent derangement of the inferior radio ulnar joint. If this occurred early open fixation was required. In fracture dislocation of the upper end of the humerus he believed that open operation would be needed less often if traction was applied to the arm in 90° abduction and 30° forward flexion with the patient half supine. An incarcerated medial epicondyle could be extracted from the elbow joint without open operation by the application of faradism to the flexor muscles while the patient was anesthetized.

Mr A J Lyle Bock (Hull) said the indications for operation ranged from those which were essential as in open fractures through less essential grades such as fractures requiring internal fixation to obtain union, small fragments in fractures involving joint and cases showing failure to maintain adequate reduction of two or more bones in one limb. In the first group operation was *essential* as for example when a screw was applied to reduce the pelvis of a mobilization. Damers still existed in spite of penicillin. Good judgment was needed and the good surgeon would plan his treatment not only upon his own ability but also upon the circumstances in which he was working.

Col H R Sheppard (RAMC) said that the open operation delivered union in the proximal humeral shaft was required with splints afterwards. When closed treatment was used Mr W R D Mitchell (Plymouth) said that operation if necessary should be done within the first two or three days. But Mr B Whitcomb (Hull) thought that Mr Sheppard's opinion (Hull) tied the value of operative treatment of fractures in the region of the femoral shaft to a point where a screw was a valuable asset for the elderly patient. Mr A D Le Vail (Hull) described a greenstick fracture of the radius which was treated that day of the tibia cases treated infected. This and the lateral point of a ray seemed to occur as a major factor in the high point of view. Mr K W Butler (Cambridge) used a special plan for operative treatment in old people. It could at times give them freedom from passive fixation. Mr James Knell (Glasgow) considered that Mr McIlrland had presented a well balanced statement of the operative treatment of fractures in general and he felt that the aim must always be to obtain the maximum of function with the minimum of risk.

Mr McIlrland in reply said that while operation would still be necessary where function would otherwise be impaired, he wished to say as emphatically as possible that while operations on closed fractures were to be pitied and completely condemned.

### Treatment of Acute Haematogenous Osteomyelitis

Dr J Frerking (Oxford) said that acute haematogenous osteomyelitis was caused by pyogenic bacteria most commonly the *Staphylococcus aureus*. The organism usually reached the bone in the blood of the nutrient artery. The process was a early phenomenon of the infection and the extent of damage to the bone depended on the area deprived of its blood supply. This area was determined by the position at the vessel of the original focus by the spread of the thrombus and later by the spread of the pus into the subperiosteal space where by the stopping off of the periosteal vessels the cortex was also deprived of its remaining blood supply. McIlrland stressed that the preservation of as good a blood supply to the bone as possible and achieved it by the combination of early intensive and sufficiently prolonged penicillin therapy, early relief of the intraosseous and subperiosteal pressures by limited conservative surgery and correct immobilization of the affected

part Success depended on the prompt use of these three therapeutic elements, and the main prerequisite for effective treatment was early diagnosis. It was necessary that every clinician and general practitioner should be aware of this urgency, since in the last resort success or failure of the treatment was determined by the time elapsing between the first symptom and the patient's arrival in the surgical ward of the hospital. Multiple drill holes were made throughout the extent of the lesion into the medullary cavity. Penicillin was given generally by intramuscular drip to the extent of 400,000 units in twenty-four hours for the first three days, 300,000 units on the fourth day, and 200,000 units on the fifth day and onwards, these amounts being varied according to the weight of the child. It was important to have the full resources of a pathological laboratory for the isolation of the organism and for testing its sensitivity.

In the subsequent discussion several speakers referred to the supposed difference in incidence as between rural and industrial populations. Dr Trueta, in reply said that it was essentially a matter of "soap and water". Where standards of cleanliness were high the incidence of osteomyelitis was low.

## SECTION OF PATHOLOGY

Thursday July 1

### Acute and Subacute Hepatitis

With Professor Dorothy Russell (London) in the chair, Professor H P Himsworth (London) opened the discussion and said that the clinical picture of acute, subacute, and chronic hepatitis (cirrhosis) did not entirely correspond to the pathological findings. The clinical features of acute hepatitis resulting from acute or subacute necrosis were well recognized. Subacute hepatitis was characterized by anorexia, enlarged liver and spleen, oedema of the ankles, and spider telangiectasis. Jaundice might be absent throughout the illness. In the plasma there was a low albumin and raised globulin content. These patients went on to develop a chronic hepatitis, and cirrhosis was seen at necropsy. Subacute hepatitis could be produced experimentally with typical lesions in the liver, leading to irregular scarring, among cases of normal parenchyma. Although the causation of many cases was obscure the level of nutrition might determine whether an acute case would recover or go on to the subacute stage.

Professor J H Dible (London) described the histological changes revealed by liver biopsy. The changes were essentially the same whether the hepatitis resulted from arsenotherapy (54 cases with 2 deaths), 'serum jaundice' (15 cases with 2 deaths), or acute idiopathic (catarrhal) jaundice (23 cases with no deaths). There was a disappearance of cells around the central vein, with swelling and degeneration of surviving cells, there were normal cells at the periphery of the lobule and some infiltration of the portal tracts with lymphocytes, plasma cells and polymorphs. The reticular pattern was well preserved, and this might play some part in regeneration. Although the lobule shrank there was an apparent increase in the supporting framework due to condensation. Bile could be demonstrated in the necrotic liver cells and endothelial cells and as bile thrombi in the bile canaliculi. The essential lesions therefore were destruction and necrosis which followed the passage of bile into the blood stream and an obstruction by bile thrombi. There was a remarkable absence of fat, but glycogen was well preserved. The usual result was complete cure, though death might occur in severe cases, or the process might resolve, leaving a liver scarred by fibrosis. In moderately severe cases young fibrous tissue might form between the bile tract and the central vein, leaving rounded islets of liver tissue with surviving cells.

Dr G W M Findlay (London) spoke of the effect of malnutrition in the causation of hepatitis, first described in 1500 when Columbus's sailors returned with jaundice as a result of their appalling diet. Hepatitis was common in the Tropics, particularly when a poor diet was accompanied by malarial infection. Dr Findlay gave statistics showing the higher mortality from hepatitis among natives in West Africa as compared with Europeans, and suggested that this was due to the low protein diet of the natives and the high incidence of malaria. He

hoped that records of all cases of hepatitis treated with casein hydrolysate would be collected, as he had seen 5 patients in coma who had recovered dramatically after intravenous casein.

Dr J A R Miles (Cambridge) drew attention to the association between bacterial infection and hepatic necrosis and cirrhosis, and particularly to the adjuvant action of bacteria on the toxic effects of chloroform and phosphorus. He had produced acute necrosis of the liver in rats on low protein diets, insufficient in themselves to cause necrosis, when chance infection with *Salmonella typhimurium* had occurred. Experimental lesions in rats had been produced with infective hepatitis material but had failed after 13 passages. Other material, including some from icterogenic serum, had failed to produce lesions.

Dr J N P Davies (Uganda) recalled the fibro-fatty liver disease seen in Africans which led to pseudo monolobular cirrhosis. Infective hepatitis and acute necrosis also occurred but led to an intermediate type of lesion similar to that described by Professor Himsworth. He thought that infections and abrupt malnutritional episodes in Africans might cause these lesions when superimposed on the fibro-fatty liver changes already present. He also suggested that the "oestrinization" which commonly appeared in male Africans (gynaecomastia and feminization of the skeleton) might play a part in the high incidence of primary hepatic carcinoma in Africans, and thought that the role of the endocrines in liver disease should be studied.

Dr J Gillman (South Africa) said that the genesis of cirrhosis was different in South African natives from that in India and the USA. He made a plea for a world survey of cirrhosis in different groups in different states of nutrition.

### Prophylaxis of Virus Infections

With Dr R I N Greaves (Cambridge) in the chair, Dr C H Andrewes (London) opened the discussion and said that vaccines made from viruses inactivated by formalin or ultraviolet light might give useful and safe protection—for example, in influenza—but this protection was not of long duration. Attenuated living viruses gave protection for a longer period, and the 17D strain yellow-fever vaccine was an ideal vaccine with a trivial general reaction and long immunity. Many viruses grown on eggs altered enough to allow of suitable prophylaxis without reaction—e.g., influenza, mumps, and measles. The existence of numbers of serological strains, however, complicated the task. In influenza strains A and B were unrelated antigenetically and epidemiologically, A being responsible for epidemics every two to three years and B every four to six years. Some success with influenza vaccines was achieved in 1943 and 1946 but they were a complete failure in the 1947 epidemic. To study variations and to collect strains from all sources the World Influenza Centre had been set up at Hampstead. He described the experimental production of immunity by the interference phenomenon. Ferrets infected with an influenza B strain which had little effect on them were later infected with known virulent influenza A with no ill effect. Later contact exposure was also without effect. This might be a pointer to artificial virus immunity, as the phenomenon also occurred with serologically unrelated viruses. He described the recent developments in the field of prophylaxis against mumps, measles, rubella, rabies, and the common cold. The work on the common cold at the Salisbury centre had not yet reached a conclusion. He described attempts at prophylaxis of the common cold with bacterial vaccines as flogging a dead horse, and thought that the volume of controlled scientific evidence available was enough to have killed the horse.

Professor R Hare (London) agreed that it was still impossible to protect humans against many of the commoner virus infections. The study was difficult because of the lack of susceptible animals and of the technical difficulties in the preparation of large quantities of virus vaccines even from eggs—themselves in short supply. Inactivated viruses on the whole were less satisfactory than attenuated vaccines. Even if they appeared to protect animals they often fail to protect humans, especially under field conditions.

Professor W I B Beveridge (Cambridge) was more optimistic in his suggestion that, while immunization was judged by its poor results in the individual, herd immunity might be greatly

increased by large-scale immunization even though there were failures in individuals. Individual immunity depended on contact between the virus and circulating antibody. If the route of infection was by the blood stream as in yellow fever and the exanthemata a basic immunity sufficed, as antibody production was greatly increased during a long incubation period. Invasion without contact with the blood stream occurred in influenza as the virus was spread over the lung mucosa. Many adults had circulating antibody but no immunity to influenza. He thought that greater attention should be paid to the part played by allergy, which could concentrate antibody at the site of infection. A further field of investigation was the removal of cell receptors for viruses by chemical methods.

Dr M G P Stoker (Cambridge) recalled that during the war there were many instances of severe smallpox in vaccinated patients. Some were due to long intervals since vaccination and others had been vaccinated only after exposure. Many vaccinations failed because the "immediate reaction" was accepted as a criterion of immunity, whereas it was an indication of sensitivity to vaccine not necessarily associated with immunity. In spite of theoretical objections Nagler's technique for estimating vaccinal antibodies by inhibition of haemagglutination might help in assessing protection. Vesiculation was necessary for an increase in immunity, and primary or accelerated reactions should alone be regarded as successful "takes". Egg virus was satisfactory, and the ratio between active and inactive virus might be important because of the interference set up by inactive virus particles. Most centres agreed that the minimum of active virus laid down by the League of Nations was too small.

Dr G W M Findlay (London) said that in the war 50,000 Europeans and 250,000 Africans had been immunized with yellow-fever virus and the war could not have been won without this great achievement. There were only 3 cases of yellow fever among these Europeans in spite of civilian outbreaks of normal proportions. The French had now immunized between 4 and 5 million people in their colonies, but our programme had now ceased. Jenner had first described the phenomenon of "interference" between two viruses, herpes and vaccinia, is long ago as 1804.

Dr C H Lack (London) asked whether immunity to smallpox was related to the survival of virus at the site of inoculation. He had recovered virus locally after three months, and a Japanese worker recently reported recovery 10 months after vaccination. He also thought that the effects of certain viruses might depend on the presence of hyaluronidase producing cocci which could disseminate the virus over a wider area of susceptible cells.

#### Strangeways Research Laboratory

Dr A F W Hughes delighted the visitors from the Section of Pathology with a beautiful demonstration of mitosis in tissue culture material under phase contrast illumination. A film shown by him indicated the differences in mitosis in such species as the newt and the xenopus as compared with young fibroblasts. Prophase, metaphase, and anaphase were clearly seen as well as the hyperkinetic activity of the nuclei and protoplasmic bodies. Miss M H Hardy produced well formed hair follicles from embryonic mouse skin and showed the several stages in the process.

Dr I Lasnitzky compared the action of irradiation on malignant tissue growing *in vitro* and *in vivo* and pointed out the considerable difference due to the secondary effects *in vivo*. Two thirds of the damage done by irradiation is the delayed vascular effect and only one-third is due to the immediate effect on the cells. Dr A Glasmann and Dr F G Spears demonstrated their method of histological assessment of the radiation treatment of cancer. They base their prognosis on a chart showing the relative numbers of mitotic cells and resting cells as compared with the differentiated cells and the degenerating cells. In a series of 1,000 cases of carcinoma mainly of the cervix and buccal cavity their histological assessment given one or two weeks after radiation had been correct in 90%.

Electron micrograph studies of growing *M. tuberculosis* bacilli were shown by Drs E M Brieger and V E Cosslett. The growth consisted of short dark rods which later became elongated. Between these two stages vacuoles appeared in the bacilli.

## SECTION OF PHYSIOLOGY, INCLUDING BIOCHEMISTRY

Thursday, July 1

### Physiological Basis of Neuromuscular Disorders

With the president, Professor A C Chibnall (Cambridge), in the chair, a discussion was held on the interpretation of neuromuscular disorders, and in particular the bearing of such interpretation upon the evidence for chemical transmission of the excitatory process from nerve endings. Sir Henry Dale, in opening, said that the theory of chemical transmission at peripheral autonomic endings might presumably be taken as accepted. This had not had much effect on clinical medicine, except on the interpretation of the actions of atropine, physostigmine, and the like. Loewi's observation of the abnormal sensitivity of the pupil to adrenaline in Graves's disease was recalled and the question raised whether such conceptions as "vagotonic" and "sympathetonic" could be given a clearer experimental basis. The possibility of "histaminergic vasodilators" was mentioned, but the consideration of their clinical significance belonged rather to the discussion on antihistamine drugs. Of more importance for neuromuscular disorders was the evidence suggesting chemical transmission, by sudden liberation and sudden removal of acetylcholine, at ganglionic and at nerve-end plate synapses. This theory had allowed a much clearer conception to be formed of the modes of action at these junctions of curarine on the one hand and of physostigmine and its analogues on the other. It made it possible to differentiate the action of botulinus toxin paralyzing the actual nerve endings or their mechanism for releasing acetylcholine, from that of curarine, which left the nerve endings and the release of acetylcholine from them unaffected but made the motor end plate insensitive to its stimulus.

The action of tetanus toxin in producing local tetanus could similarly be located at the nerve endings which appeared to lose the power of holding, but not of synthesizing acetylcholine and also lost part of their normal cholinesterase. Recent studies of myasthenia gravis and of the alleviating effect upon it of anticholinesterases afforded the most obvious example of the value of the chemical transmission theory for the understanding of neuromuscular disorders. Sir Henry Dale also mentioned congenital myotonia and recurrent familial paralysis though recent observations seemed to show in both cases that the abnormality of function was in the muscles. To what extent could the mode of transmission at peripheral synapses be carried by analogy to the central nervous system?

Professor F R Miller (University of Western Ontario) showed a number of graphs illustrating the action of acetylcholine on the hypoglossal nucleus and the respiratory centre. He began by summarizing earlier work on the effect of eserine and acetylcholine on the cerebral cortex and masseter muscle of the rabbit. An attempt was then made to determine whether acetylcholine would act locally on a motor nucleus and for this purpose the hypoglossal nucleus was selected. Eserine and acetylcholine were shown to enhance transmission at the connecting synapses. Changes in respiration and convulsive disorders were recorded. It appeared that acetylcholine must act directly on the inspiratory centre. The results were similar to those obtained by the injection of small amounts of acetylcholine into the cord circulation. There appeared to be evidence that the mode of transmission at the peripheral synapses might be extended to the central nervous system.

Dr W S Feldberg (Cambridge) said that cholinergic nerves contained definite but limited amounts of acetylcholine bound to some tissue constituents. Any acetylcholine released by the nerve impulse was at once replaced by synthesis. The nervous tissue however was unable to build up a store of acetylcholine greater than its normal physiological complement. Synthesis therefore was closely linked with and dependent upon the release. The mechanism of the synthesis at the motor endings could be studied in any part of the nerve fibre. He described the synthesis under conditions in which the enzyme remained attached to the tissue and with other methods by which it was brought into solution. The results indicated that some at least of the motor and sensory pathways consisted of chains of neurons which were alternately cholinergic and non cholinergic in character.

Dr Bernard Katz (University College, London) gave a brief survey of the chain of events by which a message was relayed within a motor unit, and discussed the essential differences between unicellular and synaptic transmission of the excitation wave. Three principal links in the neuromuscular transmission chain which could be weakened or broken experimentally were (1) liberation of transmitter, (2) its reaction with the muscle receptors, and (3) initiation of the muscle impulse. Discussing the effect of curarine, he said that curarine blocked nerve-muscle transmission but the block was perfectly reversible. In a weak curarine block a single nerve impulse arriving at the nerve muscle junction produced no effect, but two or more were able to restore the junction.

Dr Andrew Wilson (University College) gave a short account of attempts to influence neuromuscular conduction in patients with myasthenia gravis by inhibiting the cholinesterase activity of the blood with diisopropyl fluorophosphonate (DFP) and with "prostigmin". Small doses of DFP had been given to 9 cases of myasthenia gravis. In 4 cases treatment was abandoned, owing to the patients' tendency to have nightmares and vivid dreams but in the other 5 the favourable effect on the signs and symptoms of myasthenia gravis was maintained for from 16 to 24 months. The clinical effects produced by the intra-arterial and intramuscular injection of DFP were compared with those produced by the similar administration of prostigmin.

Dr C A Kcele (Middlesex Hospital) discussed the pharmacological action of the condensed alkyl phosphates hexaethyl tetraphosphate (HETP) and tetraethylpyrophosphate (TEPP), which was very similar to that of eserine and prostigmin. These compounds were powerful anticholinesterases. TEPP was about four times as potent as HETP, and both substances had actions which lasted much longer than those of eserine and prostigmin, but not so long as that of diisopropyl fluorophosphonate. TEPP was effective in the treatment of myasthenia gravis when given by intramuscular injections or by mouth. With single injections it was half as potent as prostigmin, its peak effect occurred in about one hour as compared with twenty to thirty minutes for prostigmin, and after a single injection the effects of TEPP lasted about twice as long. With repeated injections its effect was markedly cumulative. By mouth it was much more effective than prostigmin. The visceral and side effects of the two compounds were similar.

Dr G L Brown (London) was prevented owing to the lateness of the hour from presenting his paper describing recent work on myotonia.

## SECTION OF PREVENTIVE MEDICINE

Thursday July 1

### Acute Poliomyelitis

With Dr F Hall, vice-president, in the chair, Dr William Gunn (London) delivered the opening occasional paper on "Acute Poliomyelitis: Epidemiology and Control," illustrating it by slides and charts. He said that against a background of steadily receding importance in medicine epidemic diseases included at least one which, like the menace of war, remained a persistent cloud on the human horizon. By no means a new disease, acute poliomyelitis had in recent decades acquired special malignant characters that were expressed in periodic explosive prevalence and high clinical severity. Comparison with influenza and possible association of the two with two world wars was inevitable. Differences were more striking than resemblances. In both the causative agent had been isolated, but effective immunization techniques had not ensued. During epidemics both tended to be particularly lethal, with selective preference for young adults. Attacks appeared irrespective of previous health, social class or environment.

Differences between the diseases included immunity from subsequent attack after poliomyelitis, patchy and circumscribed localization of outbreaks, frequent contamination of water supplies, and high ratio of latent or abortive to clinical attacks in comparison with influenza. Nor had the relation to war been uniform. Influenza followed the first world war but unexpectedly failed to materialize after the second.

Vaccines had proved either ineffective or dangerous in cases of poliomyelitis. Passive immunization with immune-serum was applicable only in special circumstances. The greatest success in limiting the spread of infection was based on an assumption that transmission was by droplet nuclei from the upper respiratory mucosa—hence restriction of travel, avoidance of places of close assembly, and segregation of suspects and contacts. The influence of temperature and humidity in evoking or accelerating epidemicity had not been fully investigated. It was of interest that the largest epidemic in our history had coincided with one of the hottest summers on record.

Dr F W Bunting (St Helens) outlined the investigation made into an epidemic occurring in a country area. He emphasized that here was an infectious disease where a few reasonable precautions could be taken by members of the public on their own initiative. Where more rigid isolation of the actual case was required, and during epidemics a firm line should be taken by the authorities to prevent children attending cinemas. A trained team of investigators should be kept in readiness for the onset of a possible epidemic, to work in conjunction with the local medical officer of health and his staff.

Dr J C R Buchanan (Fiji) said that although poliomyelitis was seldom recorded in epidemic form in tropical countries it was not safe to assume that a hot climate *per se* was protective. Recent epidemics in the Solomons reached a known case incidence of upwards of 2 in 1,000. There was more likely to be a latent endemicity, but we still did not know enough to show what the precipitating factor actually was.

Dr E D Irvine (Dewsbury) said that during epidemic periods dental gas anaesthesia should be better controlled. The use of rebreathing apparatus by numerous persons was a probable risk. Dr J Alison Glover (Berkhamsted) emphasized the impossibility of attempting to isolate carriers. The suspension of tonsillectomy and the effective chlorination of swimming-bath water were obvious measures. Dr Josephine W Webb (Eton) said that registration of carriers, if based on contact and the occurrence of pyrexia, was impracticable.

Dr H S Banks (London) said that notifications of poliomyelitis in recent years had included a large number of non-paralytic cases and that factor should be allowed for in comparing recent with former notifications. The abortive case could not be diagnosed with any degree of accuracy in this country, at least by an agglutination test. It was also too optimistic to say that the cell-protein dissociation factor in the spinal fluid clinched the diagnosis in the non-paralytic case, since there were many exceptions. Did the epidemiological facts warrant the assumption that the virus in the pharynx was more highly infective than that in the faeces? Field studies might be directed to that point with a view to determining the limits of the usual infective period of the disease. Was the fact that virus might persist in the stools as long as 10 weeks of little importance in infectivity? There was no real evidence that serum or gamma globulin had any place in prophylaxis.

He deprecated the issue of the many instructions from public health departments in 1947 for the control of the disease that were unjustified by existing knowledge. When poliomyelitis was epidemic nothing was gained by attempts at sterilization of faeces in the home. Prohibiting public meetings even of children was unwarranted without more exact knowledge of its efficacy. Little could be done in the administrative control of the disease except to avoid tonsillectomy (but not necessarily other throat, nose, or dental operations) and to encourage general hygiene, especially the washing of hands.

### Morbidity Statistics

In a paper on "Ascertainment and Use of Morbidity Statistics" Dr P L McKinlay (Scottish Health Department) spoke of a growing dissatisfaction with the inadequacy of our basic health information. Available sources of routine statistics fell far short of the desirable in failing to cover important sections of the population, in omitting minor ailments, and by appreciable inaccuracies, especially of certified cause of illness. In addition to machinery for the provision of routine data there should be facilities for carrying out special morbidity inquiries to elucidate points emerging from analysis of routine information. Hospital data, because of their selective nature, gave a distorted picture of frequency, type, and severity of illness. Recording in hospitals should be directed principally to the

solution of special problems associated with particular diseases and assessment of therapeutic measures

Dr J Maddison (Twickenham) spoke of the many factors which might have to be considered in trying to arrive at the cause of illness. That made it difficult for any medical man working single-handed to institute special inquiries or to carry out the research himself. It was desirable for clinicians to understand more about statistics so that they could give effective co-operation. Medical officers of health should have available the assistance of a team of investigators comprising a research medical officer, a statistician, clerical assistants, punch-card machinery, a calculating machine, and field workers for special inquiries. Just as to day the M.O.H. referred clinical cases to experts, so should he refer his statistical and research problems.

Mr W. P. D. Logan (London) briefly outlined how the General Register Office dealt with morbidity statistics for sickness surveys, registration and follow-up of cancer, hospital investigations, and school absenteeism.

## COMBINED MEETING OF SECTIONS OF CHILD HEALTH AND RADIOLOGY

Friday July 2

### Malignant Disease in Infancy and Childhood

A combined meeting of the Sections of Child Health and Radiology discussed malignant disease in infancy and childhood, with Sir Leonard Parsons (Birmingham) in the chair. Opening the discussion, Professor Wilfrid Gaisford (Manchester) said that the importance of malignant disease in paediatric practice had been thrown into relief by the decline in mortality from infectious diseases. Most children dying from malignant disease were under 5 years of age. Not all malignant cases were curable. Certain forms of malignancy if treated early carried an increasingly good prognosis. The majority of curable cases of cancer also occurred in children of less than 5 years. Intracranial tumours, leukaemia, and kidney tumours were the three commonest forms of malignancy. Astrocytoma and medulloblastoma were the commonest intracranial tumours and were often curable. Radiotherapy gave good results in cases of medulloblastoma and neurosurgery in cases of astrocytoma. Improvement of symptoms within a week of beginning radiotherapy was suggestive of medulloblastoma. In cases of medulloblastoma, unlike other intracranial tumours, the basal metabolic rate was raised. Diagnosis was often delayed. Staggering was a common first symptom, and others were vomiting, headache and pains in the legs. Vomiting might persist over weeks and months and was cyclical in character in 4 out of a series of 14 cases, 9 of these children were alive three years after the diagnosis was first made.

Abdominal swelling in an infant called for examination to exclude Wilms's tumour. In a series of 15 patients with Wilms's tumour 10 died within two years and 5 were alive three years after the diagnosis. The first symptoms or signs were swollen abdomen (6), haematuria (4), abdominal pain (3), and a palpable tumour (2). Wilms's tumour might give rise to unexplained pyrexia. Suprarenal neuroblastoma were extremely radio sensitive, Wilms's tumours were not. A painless enlargement in the scrotum should raise the question of carcinoma. The inguinal glands were enlarged in the absence of scrotal involvement. X-rays would reveal lung metastases, which were not uncommon. The prognosis was good in the absence of metastases. Statistics suggested that leukaemia was on the increase, early diagnosis was difficult. In contrast with leukaemia lymphosarcoma and Hodgkin's disease were radio sensitive. Cure could only be hoped for in lymphosarcoma. The presence of a cardiac bruit, fever, and limb pains in leukaemia could lead to confusion with rheumatism. Professor Gaisford said that some tumours (mainly sarcomata) were congenital. Others, such as retinoblastoma and neurofibromatosis appeared to be influenced by genetic factors. Neoplasms appearing in childhood might affect growth and metabolism. Treatment might be curative or palliative.

### Radiological Diagnosis

Dr C. G. Teall (Birmingham) emphasized that radiology was not a short cut to diagnosis. Radiographic examination

could not establish the exact nature of a lesion or whether it was or was not malignant in the early stages of disease. Kidney tumours in the early stages showed a dense uniform shadow which might displace the intestine. Intravenous pyelography revealed renal deformities but could not differentiate embryoma from neuroblastoma, though it might assist greatly in assessing the condition of the opposite kidney. In the late stages Wilms's tumour was suggested by lung metastases, and neuroblastoma by secondary deposits in the skull and long bones. A retro peritoneal sarcoma displaced the kidney forward. The kidney shadow was large or small according to whether the radiograph was taken with the patient supine or prone. X-rays were of value in localizing intracranial tumours, the majority of which were subtentorial. Increased intracranial pressure with a rapidly growing tumour might bring about opening of the sutures. Ventricular dilatation resulting from back pressure could be demonstrated by ventriculography. Erosion of the dorsum sellae in the presence of cerebral tumours was less common in children than in adults. A high proportion of tumours of Rathke's pouch showed calcification. Osteogenic sarcomata could not be differentiated radiologically from Ewing's tumour in the early stages, and either might be indistinguishable from inflammation. Osteogenic sarcomata were radio insensitive, Ewing's tumour might benefit from radiotherapy. The use of biopsy should be accepted in order to make an early diagnosis. Certain bone changes, including a form of irregular cortical absorption were typical of leukaemia. Dr Teall said greater use should be made of radiological investigation in doubtful cases.

### Radiotherapy

Professor J. S. Mitchell (Cambridge) said the treatment of malignancy in children emphasized the shortcomings of modern radiotherapy. It was probable that gross structural chromosome changes formed the basis for the degeneration and death of cells following irradiation. Inhibited synthesis of thymonucleic acid might explain the mitotic inhibition induced by radiation. The associated disturbed nucleic acid metabolism might be related to increased cell differentiation. The formation of a heparin like anticoagulant was specially important in children in relation to dosage. In children as compared with adults special care was necessary in considering the effects of radiation upon the epiphyses, the endocrine glands and the lens and in producing late vascular changes. The distinction between radio curability and radio sensitivity was accentuated in children. It might be assumed that effective radiotherapy in children called for methods of fractionation and for time factors differing from those employed in adults. The treatment of choice for renal tumours was surgery followed by irradiation in early cases and pre-operative irradiation and surgery or radiotherapy alone with a long over-all time in late cases. Surgical treatment with post-operative irradiation in cases of retinoblastoma was discussed. In unilateral retinoblastoma excision of the eye and extensive removal of the optic nerve were essential. If the optic nerve was involved a radon seed should be implanted. For bilateral ocular involvement radon seeds might be sutured to the sclera. In cases of cerebellar medulloblastoma irradiation of the anterior cerebrum should be omitted owing to the possibility of delayed vascular changes. Ewing's tumours called for radical treatment. Professor Mitchell discussed a small series of cases of malignancy in children and adolescents. The series included a case of radio curable rhabdomyosarcoma in a boy aged 17 years. All apparently cured cases of malignant disease in children should be systematically followed up. The use of radio active isotopes in children was contraindicated even for the purpose of tracer investigations.

### Pathology

Dr A. M. Barrett (Cambridge) grouped tumours in childhood into those more common in childhood than adult life, those occurring at any age, and those which were more frequent in the adult subject. The embryonic tumours were unlikely to result from exposure to external carcinogenic factors. Recent studies had emphasized the multicentric rather than the unicentric background to these tumours.

Dr Frances Braid (Birmingham) mentioned a case of Wilms's tumour in an infant of 7 weeks. The symptoms suggested pyloric

stenosis. The baby was alive 2½ months after radical surgery. Dr R M Mayon-White (Cambridge) mentioned the necessity for the minimum of handling of a Wilms's tumour in the interval between diagnosis and the commencement of therapy. Professor G B Fleming (Glasgow) drew attention to the difficulties of differentiating these tumours from tuberculomata and from abdominal tuberculosis. Professor R W B Ellis (Edinburgh) emphasized that although malignant disease was rare in children benign tumours—for example, naevi—were extremely common. Certain benign tumours were potentially malignant in later years.

Replying to Dr Janet Roscoe (Cambridge) Dr Teall said that intravenous pyelography was practicable in infants aged 2 and 3 weeks. Dr S Cochrane Shanks reinforced Dr Teall's plea for co-operation between clinicians and radiologists and instanced the value of discussions.

### The Weights of Normal Neonates

In the afternoon a demonstration was arranged at the Cambridge County Maternity Unit. Dr Janet Roscoe (Cambridge) described preliminary studies carried out on the weights of normal neonates in the first ten days of life. All feeds had been complemented with dried milk in 203 infants during the first three days of life, 130 infants received breast milk only. The post-natal weight loss was less in infants receiving complementary feeds. Recovery from initial weight loss was more rapid in infants fed on the breast alone, and on discharge on the ninth day their weights compared favourably with the weights of babies on complementary feeds.

## SECTION OF RADIOLOGY

Thursday July 1

### A—RADIODIAGNOSIS

#### The Small Intestine in Nutritional Disorders

With the president, Dr S Cochrane Shanks (London), in the chair, Dr R A Gregory (Liverpool) surveyed the physiology of intestinal movements. He said that the motility of the small intestine determined to a large extent the normal progress of digestion and absorption by mixing the intestinal secretion with the food and bringing this into contact with the mucosa, and by moving the contents down the intestine at a rate commensurate with the progress of digestion and absorption. The results of observations and experiments on humans and animals indicated that certain forms of movement were consistently found during digestion: (1) "pendular" movements, consisting in gentle waves of contraction which pass repeatedly down a segment of intestine causing it to lengthen and shorten rhythmically; (2) peristalsis, a strong slowly moving double wave of contraction above and relaxation below some point of stimulation; (3) "segmentation," the repeated and rhythmical division of a length of intestine into several segments by relatively stationary contraction-waves; and (4) "rush waves" a rapid vigorous contraction extending for considerable distances down the bowel, seen characteristically in diarrhoea and similar conditions as well as during normal digestion. The gut as a whole was "polarized" in that the movements tended to pass downwards.

The evidence that peristalsis resulted from a local reflex (myenteric reflex) in the enteric plexuses, while segmentation and pendular movements were of myogenic origin was discussed in relation to the structure of the enteric plexuses and other work. The extrinsic nerves normally exerted a mutually antagonistic influence on the general activity of the intestine, complete denervation of the small intestine was followed by a "paralytic" increase in tone and motility lasting several days. The splanchnic nerves formed the reflex pathway for intestinal inhibition (ileus) produced by afferent impulses from the peritoneum, abdominal organs, etc., splanchnic section or anaesthesia of the abdominal ganglia or of the spinal cord abolished the inhibition. A number of observations indicated that the passage of intestinal contents down the gut was controlled by the acidity, and perhaps also the chemical composition via reflexes originating in chemoreceptors in the mucosa.

Dr F R Berridge (Cambridge) had examined 78 cases in north Germany in 1946 under the auspices of the Medical Research Council. There were many nutritional disorders. All his cases had at some time suffered from famine oedema and many were oedematous at the time of examination. In the radiological examination he gave by mouth 100 g of barium sulphate suspended in 100 ml of normal saline. The Miller-Abbot tube was time-consuming and had no special advantages. The patients were all examined lying down. In the normal subject the mucosal folds decreased in height and number from the upper to the lower end of the small intestine. The lumen of the gut narrowed from above downwards and movement decreased from above downwards. Normally the barium entered the small gut in a continuous stream and remained as such until it reached the colon.

Of the 78 German cases 32 were normal and 46 abnormal. The latter showed fragmentation of the barium column, mostly in the mid-jejunum and upper ileum. The rugae, whose normal width was about 2 mm, were widened to 4 mm and were more widely separated. Flocculation also occurred—i.e., fragments of barium remained in the jejunum and ileum after the main mass of barium had passed on. Previously this feature was said to occur only in steatorrhoea. Another feature he found, also seen in steatorrhoea, was a smooth outline of the upper jejunum.

The only common factor in all the abnormal cases had been loss of weight and at some time famine oedema. The vitamin deficiencies had been so various that no particular one could be attributed as cause.

Dr Wilfrid Sheldon (London) contributed a paper on coeliac disease. He said that the term "coeliac syndrome" was criticized adversely because it was maintained that by clinical examination and laboratory investigation other causes of steatorrhoea, abdominal distension, and wasting in young children could be differentiated. Those conditions included abdominal tuberculosis, *Lambia* infection, chronic septic infection, and fibrocystic disease of the pancreas. He accepted the value of analysing the enzymes in the duodenal juice, and of trypsin in particular, in distinguishing between pancreatic fibrosis and coeliac disease, and he outlined the dietetic treatment of the former condition. He questioned the customary interpretation of faecal-fat analysis and the flat oral glucose absorption curve in coeliac disease. While faecal-fat analysis might have some diagnostic value in coeliac disease it was not a good guide to treatment.

Dr D A K Black (Manchester) said that the most important small-gut disease in adults was steatorrhoea—a bad name for the defect was certainly not limited to fat absorption. Glucose was also poorly absorbed, and in severe cases of sprue even water and salt were poorly absorbed. Deficient fat absorption was partial at least 50% being absorbed, and in many cases as much as 70%. Unabsorbed fat might irritate the colon and thus cause diarrhoea. That could be checked to some extent by administering calcium salts, which probably precipitated the soluble soaps, which were less irritant.

One of the features of steatorrhoea was its pleomorphism. Some cases might have normal stools and no diarrhoea. Sprue might present as a refractory anaemia, not necessarily of the macrocytic type. This made diagnosis very difficult, and radiological investigation, particularly with the aid of drugs, was necessary.

Professor A C Frazer (Birmingham) said that he and his colleagues had attempted to produce an abnormal pattern of barium in the small bowel of normal subjects. By adding products of fat digestion to barium sulphate they had constantly succeeded both by the oral method and by intubation. Giving ordinary fat with barium did not cause segmentation of the meal. One must hydrolyse the fat. The segmental pattern could be restored to normal by giving calcium, which removed the fatty acid.

#### The Pancreas

In the afternoon Dr Kemp Harper (London) spoke on calcification calculi, and cysts of the pancreas. In ordinary radiological practice calcification was rarely seen in the pancreas perhaps partly because plain films of the abdomen were relatively rarely taken. Ludin had x-rayed 2 000 cadavers and had

### THE TEAM'S THE THING

The physician's chief responsibility is diagnosis and treatment. Eli Lilly and Company supplements the physician's skill by providing fine pharmaceuticals upon which he can place full trust. The beneficiary of this co-operative effort is the patient.

## STERAMIDE-AG.

Steramide-Ag combines for the first time in a single solution the valuable properties of sulphacetamide soluble 30% and silver vitellinate 5%.

This combination of chemotherapeutic activity and antiseptic action in Steramide-Ag can be recommended for the treatment of all conditions where the use of sulphacetamide soluble or silver vitellinate is indicated and provides a superior form of local treatment for ocular and nasopharyngeal infections.

Supplied in pipette bottles containing 25 cc

Special literature available on request

## A GREAT REPUTATION IS A GREAT RESPONSIBILITY

A reputation, once gained can be retained only by unceasing watchfulness. The fame of 'Wellcome' brand Insulins is due, not to chance but to the maintenance of untiring research and most rigid standards of manufacture. The discovery of Globin Insulin (with Zinc) and its introduction to the medical profession resulted from work carried out in The Wellcome Research Laboratories Tuckahoe New York. Globin Insulin (with Zinc) fills the gap between the rapidly-acting unmodified insulin and the slower protamine zinc insulin. Together, these three cover the whole field of insulin therapy.

### 'WELLCOME'

INSULIN (Unmodified or soluble insulin)  
20, 40 and 80 units per cc in 5 and 10 cc bottles

GLOBIN INSULIN (with Zinc)  
40 and 80 units per cc in 5 cc bottles

PROTAMINE ZINC INSULIN  
40 and 80 units per cc in 5 cc bottles 40 units per cc also in 10 cc bottles

BURROUGHS WELLCOME & CO  
(The Wellcome Foundation Ltd) LONDON

INTRODUCING A SAFE AND EFFECTIVE SEDATIVE  
AND HYPNOTIC FOR REPEATED ADMINISTRATION

from the Laboratory of

T. & H. SMITH LTD.

## TABELLÆ SEDATIVÆ

R. Tab Sedativ (Smith)

These Tablets present a new combination, providing the well-tried sedative and hypnotic property of Phenobarbitone enhanced by the analgesic and antispasmodic action of Codeine.

**INDICATIONS** Insomnia, neuralgia, cardiac neurosis, angina, bronchial and cardiac asthma, painful cough, whooping cough, causalgia, dysmenorrhœa, epilepsy, hysteria, migraine, mental disease, chorea, pruritus, and in many other conditions where a reliable combined hypnotic and analgesic is required.

EACH TABLET CONTAINS PHENOBARBITONE  $\frac{1}{2}$  GRAIN AND CODEINE PHOSPHATE  $\frac{1}{2}$  GRAIN WHICH GUARANTEES ACCURATE DOSAGE AND CONVENIENCE OF ADMINISTRATION

MAY BE DISPENSED ONLY ON PHYSICIAN'S PRESCRIPTION

Physician's Sample free  
on receipt of signed  
order

## THE MALE CLIMACTERIC

Climacteric symptoms occur in men as in women, the result of decreased function of the sex glands.

The symptoms are as effectively relieved by Androgenic as are those of women by Oestrogenic therapy.

Carcinoma of the prostate is the chief contra-indication.

The use of sex hormone to increase fertility in infertile couples is being and has been studied.

Testosterone Organon (Neo-Hormonal) is available in the form of 15 mg suppositories, a preparation in 5, 10 and 25 mg ampoules and by mouth as Methyl Testosterone (Neo-Hormonal (H)) in 5 mg capsules. Refills and abstracts on request.

## TESTOSTERONE

by

### NYLON MONOFILAMENT

Non-absorbable  
SURGICAL SUTURES

**Radiophosphorus ( $P^{32}$ )**—Physical properties half life 14.3 days Radiation negative beta rays only Energy maximum  $1.712 \pm 0.008$  Mev, mean 0.70 Mev Range in water maximum 0.82 cm Assuming a constant concentration, 1 microcurie per gramme of tissue delivered 38.5 r per 24 hours, so that without allowance for excretion a dose of 1 r was delivered by 1.26 microcuries destroyed per kg, or assuming an effective half life of 11 days to allow for excretion, 10 r was given by 1.15 microcuries destroyed in a 70-kg patient These calculations were based on the relation that 1 r of radium gamma radiation with normal filtration corresponded to the absorption of 93.1 ergs per gramme of water Other published data on dosage, particularly by American authors, had been based on air absorption with a conversion factor of 83 ergs per gramme, and the values given (for example by Low Beer and Kamen) would therefore require a corresponding adjustment for comparison The differential absorption ratio must also be taken into consideration, and approximate values were 1.5 for normal red bone marrow and 2.5 for normal lymph nodes In practice these differential absorption rates were too low for successful therapeutic purposes, and the most promising applications appeared to be in the case of leukaemia and allied diseases and especially for polycythaemia vera

**Radio iodine (8-day,  $I^{131}$ )**—Physical properties half life 8 days Radiation negative beta rays and gamma rays Energy beta rays, maximum 0.6 Mev, mean 0.205 Mev, gamma rays, 0.367 and 0.08 Mev (85-90%), 0.65 Mev (10-15%) Range in water of beta rays maximum 0.22 cm 1 millicurie per gramme of tissue delivered 7.83 r per minute, so that without excretion 1 microcurie destroyed per gramme gave a dose of 130 r, or, assuming an effective half life of 6.32 days to allow for excretion, this dose was reduced to 103 r It should be noted that the normal thyroid weighed  $25 \pm 5$  g and contained 10-15 mg of iodine

An example of the type which might occur in practice was hyperthyroidism—for 80% fixation of  $I^{131}$  in a thyroid weighing 60 g, 4 millicuries administered by mouth would produce a total dose of approximately 5,500 r in a mean time of 9.1 days, carcinoma—assuming in this case 50% fixation in a tumour weighing 300 g, 58.4 millicuries gave a total dose of about 10,000 r

In the discussion which followed Dr Leo Wislicki asked how to relate doses of radioactive elements to the weight of various types of goitre, and also if it was possible to measure the distribution of radioactive elements in the different parts of the living animal

Professor Mitchell agreed that most calculations and work done with models of thyroids were subject to very serious limitations, and great accuracy was not to be expected, all gave results based on an average concentration assuming uniform distribution Dr McFarlane replied that there was considerable information on distribution and mentioned particularly sodium and iodine although most of the results were based on animal experiments With an external counter the accuracy of localization was not very high Dr C. J. L. Thurgar (Newcastle-upon-Tyne) wanted to know what happened in the treatment of carcinoma of the thyroid by radioactive iodine, to that proportion of the iodine which was not fixed by the tumour He stated that to deliver a dose of 10,000 r to the thyroid with  $I^{131}$  it was necessary to give between 50 and 60 mc of the isotope of which 50% was fixed Was the remainder excreted rapidly, and did the heavy dosage employed result in any undesirable side-effects using either of the radioactive isotopes of iodine? Professor Mitchell explained that part of this was excreted fairly rapidly, although the possibility of renal damage in the process and storage elsewhere must always be considered Dr F. T. Farmer (Newcastle-upon-Tyne) said it seemed clear that except in the case of iodine the selective absorption of isotopes in various parts of the body was very slight and held little promise for the treatment of tumours The alternative possibility of preparing an organic compound which was taken up by the body and concentrated into tumour tissues, and which could be made radioactive by the inclusion of a suitable isotope was one which seemed to hold considerable promise, and he asked what progress had been made in this direction Professor Mitchell replied that much work had been done, with negligible results An alternative approach was the use of inactive substances to increase

the subsequent uptake of the radioactive materials, an example being the administration of thiouracil

### Discussion

Dr Frank Ellis (London) referred to the example quoted by Professor Frisch of K-electron capture in vanadium<sup>50</sup> followed by the emission of  $\gamma$  radiation, and asked whether it would be possible to obtain an element suitable for absorption in tissue and transforming in this way with the emission of characteristic radiation of wavelength about 4 Angstrom units, which would be expected to be most effective for chromosome breakage Professor Mitchell thought the substances of this type would be difficult to obtain, but drew attention to the possibility of using isotopes emitting alpha particles with energies of the order of 6 Mev and a range of 15  $\mu$ , which would have a high efficiency in chromosome breakage Professor Frisch emphasized that K-capture transformation occurred mainly with elements heavier than calcium—for example, in the region of zinc and nickel—but that consequently the characteristic radiations were harder than was desirable Dr Ellis asked Professor Mitchell about the genetic effects likely to be caused by tracer amounts of isotopes Professor Mitchell explained that such effects would be limited to a small fraction of the population and in most cases would be of the nature of deleterious recessives and so not visible for generations, also translocations and semi-sterility would be probable types of changes Dr Ellis described work which had been started at the London Hospital with thorium X injected into the bladder in order to make use of the short-range alpha particles It had been found that the thorium X was deposited on the bladder surface, and the resulting intimate contact made it possible to use smaller amounts than was at first expected When phosphorus<sup>32</sup> was used in the hope of getting greater radiation penetration there was no similar "sticking" to the surface, and much larger quantities were required It was hoped that by the choice of a suitable phosphorus compound this could be improved It was found that, for such intracavitary applications as in the case of the bladder, thorium X had advantages over the normal use of  $\alpha$  rays

## SECTION OF OCCUPATIONAL HEALTH

### Aviation Medicine Applied to Civil Aviation

Professor Ronald E. Lane was in the chair when Air Marshal Sir Harold Whittingham, opening the discussion said that aviation medicine was divided into two main sections, one which dealt with ground staff and concerned a variety of trades common to many branches of industry, while the other appertained to flying proper Emphasis was laid on the physiological, psychological, and hygienic problems concerned, particularly with regard to selection of air crew and the maintenance of their efficiency during flight He stressed the importance of safety and comfort for both air crew and passengers in civil flying and gave a brief review of the main advances in aviation medicine as applied to civil aviation These advances were divided into two groups—namely, those which had originated in Service researches during the war and those now being undertaken by research workers employed by the British Airways Corporation working in collaboration with their Service colleagues at the R. A. F. Institute of Aviation Medicine The chief items discussed were air sickness, air conditioning of pressurized aircraft, oxygen equipment, aircraft accidents—with a plea for backward-facing seats, flight schedules and their relation to fatigue, retiring ages for various members of air crew, seat design, safety belts, and life jackets, the maintenance of safe water and food supplies on air routes and the use of the deep-freezing technique for pre-cooked foods, and the disinsection of aircraft and other quarantine problems, including the standardization of vaccines and the technique of preparation and inoculation

### Physiology of Stratosphere Flying

Wing-Commander A. K. Stewart (Farnborough) said that, as compared with ordinary military or civil flying at altitudes up to 30,000 ft, stratosphere flying would probably be characterized by little turbulence, in addition, the moisture content

The significance of refraction in relation to general and ocular diseases was then discussed. Diabetes mellitus was the disease most commonly affecting refraction, though it was strange that, according to Sir Stewart Duke-Elder only 10% of diabetics noted any change. The change was probably due to alterations in the size of the lens, since in one unilateral aphakic patient the changes occurred in the normal eye only. Spectacles, he said, should not be ordered until the diabetes was fully stabilized.

Patients with psychosomatic disorders affecting accommodation might complain of dimness of vision due to temporary failure or irritability of accommodation. When occurring in otherwise healthy young adults this might be cured by glasses for close work only. A case of Mr H. Neame's was quoted of a girl with myopia whose sight was partially improved by glasses, but after leaving home to do war work which she enjoyed the myopia disappeared and the sight became normal. Other causes for changes in refraction included pressure on the globe by small tarsal cysts or lacrimal gland swelling, mild degrees of conical cornea, and central serous retinitis. Glaucoma was said to cause premature presbyopia, but he had never seen a case. Finally, he considered errors of refraction which might be the direct cause of eyestrain, defective vision and imbalance between accommodation and convergence. The latter was the undoubted cause of a number of squints, and in these cases defective vision might result in amblyopia ex anopsia. Psychological disorders might occur in children from defective vision, and eyestrain might set up a chain of events leading rarely, to murder or suicide. A rational view of the patient's symptoms must therefore be given him as well as a pair of spectacles.

The third speaker, Mr. Victor Purvis (London) began by saying that a busy clinic refractionist could not allow himself to remember that refraction was more than a rapid retinoscopy and a sick subjective test, but that even if time were taken to examine the patient carefully there was a difference between practice and precept and an extraordinary disparity between one surgeon and another. Refraction was an estimation of the patient's ophthalmic equipment and ocular requirements, therefore it was a matter for congratulation that prescriptions were so much alike. The aim was ocular comfort for the patient without making the test too strenuous either for the patient or for themselves. The method of retinoscopy was unimportant so long as the results were the same. Without a cycloplegic retinoscopy was inaccurate as the refraction was not taking place along the true axis, to reduce the error so far as possible the right eye should be used for the patient's right eye and vice versa.

Mr Purvis went on to discuss the advantages and disadvantages of cycloplegics, favouring the use of only as opposed to watery homatropine. Atropine he reserved for squinting children. He admitted that cycloplegics took longer to act in the coloured races and when the iris was dark. He prophesied that non-luminous mirrors would soon be outdated by the electric retinoscope. Agreeing with Mr. Recordon that speed in testing was essential since the basis of the test was contrast, he went on to say that the examiner must take charge of his patient. The attention of the ciliary muscle and of the mind must never be allowed to wander. The most accurate subjective testing was carried out with the aid of crossed cylinders, especially for estimating astigmatism with a duochrome test for the final checking. He would not put any person into glasses if they were comfortable without, whether they could see 6/5 or not, excepting the growing child who in this competitive age should be given as good sight as his fellows.

During the discussion which followed Miss Margaret Dobson (London) said that she thought prisms were useful for exophoria but not for esophoria. Mr R. F. Lowe (Melbourne) thought the relations between ophthalmologists and opticians required clarification since the surgeon could not be responsible for the refractions undertaken by opticians, who were not always accurate. Mr Lister disagreed with this, he thought the work of the majority of opticians was most accurate. Dr Jamna V. Dhurandhar (Bombay) said that many cases of presbyopia took maximum reading corrections at the age of 45. Mr Recordon replied that in his opinion this was due to distance under-correction.

Mr O. G. Morgan (London) thought that presbyopic corrections were generally too strong and that a patient should be

encouraged to leave off his glasses whenever possible. Dr J. Berkson (Liverpool) said that in presbyopes often retinoscopy suggested that cylinders were not needed, but the addition of half a dioptre cylinder would increase the vision. Dr Ryan (London) believed that more time should be devoted to the teaching of refraction and especially the interpretation of retinoscopy findings. Mr L. G. Seouler (London) had found that 60% of patients had the left eye higher than the right and this should be taken into consideration when ordering glasses with cylinders. Dr Duncan (Leicester) brought up the question of postural headache, and pseudo myopia in children, and Dr M. L. Mistry (Bombay) cited the case of a woman with bilateral dilated fixed pupils.

In the afternoon a clinical meeting was held at Addenbrooke's Hospital and films on the following subjects were shown: operations for detachment by Stallard, intra- and extra-capsular cataract extraction, strabismus and glaucoma.

## SECTION OF ANATOMY AND ANTHROPOLOGY

Friday, July 2

### Present Position of Primate Anatomy

With the president, Professor H. A. Harris (Cambridge) in the chair, Professor Frederic Wood Jones (Royal College of Surgeons of England) opened a discussion on the present position of primate anatomy. He gave a provocative review against a strong historical background and emphasized the gradual growth of that cohesiveness and concert which characterized the zoologists at the end of the nineteenth century, when it was generally accepted that Charles Darwin and Thomas Henry Huxley had filled the cup of anatomical knowledge to the full. It was only at the beginning of this century that doubt was cast on their pronouncements and the renewed use of scalpel and forceps invalidated many of their assumptions and provided facts which were at variance with Darwin's *Descent of Man* (1859) and Huxley's *Man's Place in Nature* (1863).

Professor Wood Jones said that Darwin had no first-hand knowledge of the anatomy of any primates and what he retained at second hand was strangely inaccurate. Huxley's sole contribution to the study of primate anatomy was one small paper on the brain of *Ateles* the spider monkey, and his knowledge of primate anatomy was meagre. Yet at this very epoch Richard Owen the master of comparative anatomy and St. George Jackson Mivart, the master of primate anatomy, had provided accurate information on the anatomical structure of certain primates. Their findings were entirely at variance with the anecdotal type of information dispersed by Darwin and Huxley. Moreover, Robert Bentley Todd published his great *Cyclopaedia of Anatomy and Physiology* from 1835 to 1859 and it contained Vrolik's accurate article on the "Anatomy of the Quadrumana". The speaker pointed out how Darwin confused the maxilla and premaxilla with the malar bone and how all his notions of the entepitrochlear foramen in the humerus of man were faulty through lack of anatomical examination. Reference to Todd's *Cyclopaedia* would have saved both Darwin and Huxley from their mistakes. Professor Wood Jones traced the final failure of the morphological school from Darwin and Huxley through Haeckel and Bland-Sutton, and showed how the armchair analysis of atavistic structure became fashionable. He gave a rapid survey of the accurate workers in the field from Tyson (1669) on the gorilla, Burmeister (1846) on *Tarsius* and Alan Thompson (1839) on the ovum to modern times. In particular he stressed the manner in which accurate published information on comparative anatomy was neglected so that the re-examination of the platitudes of the morphological school was long overdue. He made a plea for the recording of the complete anatomy of a wide series of members of the primates so that clarity of thought might replace the illogical discussions on man's place among the primates.

Professor H. A. Harris (Cambridge) dealt briefly with the use of radiography in tracing the comparative features of growth in the primates. As he had prepared an extensive demonstration of primate specimens with their radiographs, he limited himself to a brief discussion of the growth of the skull and the face and the eruption of the deciduous and permanent dentition indicating how the order of eruption differed in primates and man. He mentioned the wide variation in the pattern of

## Where do you find athlete's foot?

Despite the implication in the name, athlete's foot is more prevalent amongst the non-players than it is amongst players, to all of whom care of the feet is of primary importance. The introduction of 'Mycil', the new fungicide—*p*-chlorophenyl- $\alpha$ -glycerol ether—developed in the B D H Research Department, has made available to medical men a highly effective

preparation for prevention and treatment of this wide-spread infection. 'Mycil' is available as 'Mycil' Ointment and 'Mycil' Dusting Powder.

## TEMPORIS ARS MEDICINA FERE EST (OVID)

The art of medicine is generally a question of time. With the peptic ulcer patient, as is well known, the rate of healing is determined by the ulcer's freedom from irritation. By rapidly buffering excess acid and at the same time avoiding acid rebound, 'ALUDROX,' a suspension of 5.6% colloidal aluminium hydroxide in gel form, ensures rest for the ulcer. Pain is relieved and time taken for healing reduced to a minimum.

actions. He quoted Schild's demonstration that sensitized guinea pig muscle, suspended in a bath, contracted in response to histamine, after exposure to a large dose it was unaffected by a further application of histamine. Nevertheless addition of the antigen caused contraction, thus the cell responded to intrinsic histamine but not to extrinsic histamine. Such a conception might explain why antihistamine substances were good for vasomotor rhinitis but not for spasmodic asthma.

Discussing the release of histamine, Sir Henry said that the blood had been regarded simply as a vector of histamine, it should be studied as a tissue which itself might liberate histamine from eosinophil and other cells. Finally he referred to the possibility that histamine had a normal physiological function being released in small quantities to regulate the local blood supply and to Rein's statement that carbon dioxide potentiated the action of histamine. Care should be taken that antihistamines should not be used so as to interfere with this function.

Professor J. H. Gaddum (Edinburgh) said that the antihistamine substances were discovered in Paris largely by the work of Daniel Bovet, at a time when he was looking for anti-adrenaline substances. Co-operation between pharmacologists and chemists had resulted finally in the introduction in 1944 of 'neoantergan' (anthisan). In spite of the more recent introduction of other antihistamine substances, anthisan remained the best pharmacological tool, since it was more specific against histamine and less active against acetylcholine. Clinically the extreme specificity of anthisan against histamine might not be so important. Professor Gaddum described methods of testing antihistamine compounds, and pointed out that they reduced all histamine effects except its action on gastric juice. They had in addition local anaesthetic properties and a quinine-like action on the heart.

Dr R. B. Hunter (Edinburgh) discussed the clinical uses of antihistamine substances. He emphasized the need for comparative antihistamine studies in man before a new substance was introduced for clinical use. These could be carried out on the skin or related to the effects of intravenous histamine. For example the incidence of toxic effects with R.P. 3277 was much greater than with anthisan. The beneficial action was best seen in urticaria. There was a diminution of the number of lesions within thirty minutes of the first dose. Dr Hunter showed the effect of increasing the daily dose of anthisan from 0.4 to 0.6 g daily at which point the urticaria was fully suppressed. In the course of treatment the daily requirement might diminish—for example from 0.7 to 0.2 g. It was not wise to stop treatment suddenly, or there might be a rebound effect. There was some evidence that 'benadryl' was better than anthisan for the relief of itching. Antihistamine substances had little effect on established lesions and when there was oedema of the tongue or glottis adrenaline was still required. When desensitization was necessary it should still be carried out. In severe cases of hay-fever desensitization followed by the use of antihistamine drugs during the season had produced complete relief in 95% of cases. In perennial rhinitis some relief was given by dummy tablets to 34% of a group of patients but 50% obtained complete relief by taking anthisan, a relief which was accompanied by the reversion of the allergic nasal mucosa to normal.

Dr R. P. Warin (Leeds) said that the side effects of R.P. 3277 passed off before the antihistamine effects. This substance had therefore been given in urticaria in one dose at night. Side effects had not been seen the next day and the urticaria had been controlled. Observations made on 20 patients for six to nine months had shown that tolerance to antihistamine substances did not occur so far as could be seen from the size of histamine wheals in the skin.

Dr J. Shlosberg (Salford) and Dr H. G. J. Herxheimer (London) thought that antihistamine substances diminished the severity of asthmatic attacks in some cases. Dr W. Feldberg (Cambridge) said that the fact that antihistamine substances did not affect the gastric secretion might be related to the connexion between histamine action and carbon dioxide. If an animal was overventilated it was impossible to produce gastric secretion with histamine. Dr W. N. Leak (Winsford) said that the possibility of reducing the dose during treatment suggested that these antihistamine substances might lessen the formation of histamine as well as antagonize it. He mentioned the

case of a farmer who suffered from severe asthma for twenty years and recovered after the removal of a perforated appendix.

Dr Hunter replying to some discussion of the relief of itching said that the local analgesic action of antihistamines was short, while their effect on itching lasted for hours.

### Antidiuretic Hormone

With Professor A. C. Frazer (Birmingham) in the chair, Professor E. B. Verney opened a discussion on agents influencing the functions of the pars nervosa of the pituitary. He described the diuresis produced in a dog by giving water by mouth and the inhibition of the diuresis by a sensory stimulus. With O'Connor he had shown that this inhibition was due to the liberation of antidiuretic hormone from the pars nervosa. The pars nervosa received impulses from nerve cells in the supra-optic nucleus, and it was presumably through this nucleus that the sensory stimulus caused a discharge of antidiuretic hormone. Professor Verney said that the normal function of this mechanism was to keep the osmotic pressure of the plasma as nearly constant as possible. If an injection of hypertonic sodium chloride was made into the carotid artery of the dog then an inhibition of diuresis occurred and the greater part of this inhibition disappeared after removal of the posterior lobe. The response to sodium chloride was determined by the change in osmotic pressure and the term "osmoreceptors" had been introduced as a name for the receptor elements which were somewhere in the vascular bed of the internal carotid artery. The results of long-period intracarotid infusions showed that the osmoreceptors were freely permeable to and not affected by urea, less freely permeable to dextrose, and relatively impermeable to sodium chloride and sucrose. The local increase in osmotic pressure required in a forty-minute infusion on one side to reduce the urine flow during water diuresis to about 10% of its maximum was about 18% only. Water diuresis was aptly described as a condition of physiological diabetes insipidus, the antidiuretic secretion of the neurohypophysis being a hormone in the sense that its liberation was governed by the concentration of osmotically active substances, like sodium chloride, in the plasma.

Dr Mary Pickford (Edinburgh) described experiments in which the injection of acetylcholine into a dog during water diuresis caused inhibition of the diuresis. These experiments were performed when the dog was fully atropinized. The inhibition was not seen when the posterior lobe was removed. It had been possible to demonstrate that the site of action of the acetylcholine was the supra-optic nucleus. This was accomplished by making the injection directly into the nucleus. It was found that a very small amount of acetylcholine caused inhibition provided that it was injected into the nucleus, but not outside it. The precise point of injection was determined by mixing Indian ink with the acetylcholine solution. By the injection of DFP, the potent anticholinesterase, into the nucleus, a state of complete anuria had been produced followed by a period of polyuria and thirst for two to three days. Thus a temporary diabetes insipidus had been created.

Professor J. H. Burn (Oxford) said that the effect of acetylcholine on the supra-optic nucleus must be a nicotine-like action, since it occurred in the atropinized animal. They had therefore tested nicotine in the rat and had found that it produced inhibition of a water diuresis, an inhibition which was not seen in the rat after hypophysectomy. Next they had observed that inhaling the smoke of one or two cigarettes exerted an antidiuretic effect in man and that a similar effect was produced by the intravenous injection of the amount of nicotine inhaled in smoking one or two cigarettes. They had found that the inhibition produced was similar to that caused by 50–100 milli-units of posterior lobe extract. This corresponded to 10–20 milli-units per litre of blood. Further experiments by Dr E. Bulbring and Dr J. M. Walker had demonstrated that the intravenous infusion of nicotine into an anaesthetized dog led to coronary constriction. In observations on the heart-lung preparation of the dog they had found that the amounts of posterior lobe extract which when added to the venous reservoir were just sufficient to cause coronary constriction were 10–20 milli-units per litre, a concentration of the same order as that produced in the blood by smoking. Hence the evidence indicated that smoking might cause coronary constriction.

Dr W J O Connor (Cambridge) described experiments in which salt was given to dogs before and after diabetes insipidus was produced by section of tracts from the supraoptic nucleus. He said that the absence of the antidiuretic hormone did not influence chloride excretion, but the neurohypophysis determined the concentration of chloride in the urine, enabling the body to retain water during the excretion of salt. His evidence showed that only a small fraction of the maximal capacity of the neurohypophysis was required to control the full range of kidney function.

Dr G W Theobald (Bradford) said that, since very minute amounts (0.005-0.01 unit) of post pituitary extract inhibited water diuresis in man, it seemed logical to assume that amounts of the oxytocic hormone of the same order would stimulate uterine contractions. In Bradford it had been found possible to induce labour subsequent to rupture of the membranes and to augment the force of contractions in uterine inertia by means of a 1 in 10,000 solution of pituitrin given intravenously at a rate of 1 ml per minute.

Dr W Feldberg (Cambridge) said that he had obtained additional evidence for the suggestion that the nerve fibres impinging on the supraoptic nucleus acted by releasing acetylcholine since the brain in this region had a high capacity for acetylcholine synthesis.

### ORDER OF ST JOHN OF JERUSALEM

The *London Gazette* has announced the following promotions in, and appointments to, the Venerable Order of the Hospital of St John of Jerusalem.

As *Knights* Brigadier Sir W S Duke Elder, KCVO, MD, FRCS, and Dr Christopher Armstrong. As *Commanders (Brothers)* Lieutenant-Colonel W S Copeman, OBE, MD, FRCP, and Surgeon Rear-Admirals Sir H E Y White, KCVO, OBE, MD, FRCS, KHS, and C E Gresson CB, MD, KHP. As *Associate Commanders (Brothers)* Major-General A N Sharma, IMS, and Drs K B A Hamid, MBE, and P C Roy. As *Officers (Brothers)* Surgeon Captains W Colborne, FRCS, and F G Hunt, CBE, MB, RN, Prof P Farrugia, MD, Messrs F W Law, FRCS, and N G W Davidson, OBE, FRCS, Drs C Hibbert, J D Ingram, R G Selby, E K Macdonald, OBE, J L Johnston H Schloefield, J A Davies, J P J Jenkins, OBE, TD, G W H Townsend, T Hampson, MC and R Paton. As *Associate Officers (Brothers)* Lieutenant Colonels D P Nath, MB, and G D Mallioutr, OBE, MB, IMS, and Captain K B N J Vazifdar, MBE. As *Associate Officer (Sister)* Dr Chit Tin. As *Serving Brothers* Surgeon Commander C N H Joynt, MB, and Surgeon Lieutenant Commander W S Miller, MB, RN, Messrs R M Hill, MD, FRCS, and R E M Pilcher, FRCS, Drs P N Grinling, E F Brown, J G Billington, K A Boughton-Thoms, R Rodger, J S Laurie, J G F Hoslen, J Pereira, N R H Holmes W W J Lawson, A McInnes, H J Marriner, J V Tollington, Thomas Jones F J Rees, and J F Scales. As *Associate Serving Brothers* Drs A Nath, J Shubko, and V Aye Pe. As *Serving Sisters* Drs Annette G T Anderson, Marian Mixwell Reekie, Marjorie C Chappel, and Sylvia M T John.

## Nova et Vetera

### AN EARLY WORK ON MEDICAL JURISPRUDENCE

I have come across an interesting book, published in 1815, the title of which is *Elements of Medical Jurisprudence or A succinct and compendious description of such tokens in the human body as are required to determine the Judgment of a Coroner and Courts of Law in cases of Divorce Rape Murder etc to which are added directions for preserving the Public Health*. It is by Samuel Farr, MD, and includes an essay by Dr William Hunter on observations on the uncertainty of the signs of murder in the case of bastard children. The first edition was printed in 1787, and it is claimed to be the earliest work published in England on medical jurisprudence. The book is a small one, the eight chapters on medico-legal matters, the chapter on public health, and Dr Hunter's essay occupy together less than 200 small octavo pages.

The eight chapters on medical jurisprudence deal with pregnancy, parturition, divorce, rape, murder of infants, homicide, insanity, and malingering. The chapter on public health is

particularly interesting for it was written over 50 years before the first Public Health Act of 1848, the centenary of which is being celebrated this year. It is there suggested that magistrates should consult physicians of the first eminence with the idea of vesting powers in proper authorities for a general public health service—an excellent vision of things to come. Three general principles are laid down: (1) to prevent everything which may injure public health, (2) to see that sick people are properly treated, (3) to prevent the spread of infectious disease. These are three excellent propositions.

Under heading (1) fresh air, pure water-supply, and fresh and wholesome food are advocated. Unqualified practice is severely disapproved. Farr's observations on quacks are worth quoting. No one can tell how much they injure society by violent medicines the effects of which they do not see. They may introduce some fatal disease, and by efficacious ones they prevent the effects of those which are proper. Many years ago a tax was laid upon quack medicines in England, which, it was presumed, would rather tend to suppress the sale of such articles, the contrary, however, has been found to be the effect for every quack now professes that his medicine has the sanction of Government and thus is the public the more easily deluded.

Under heading (2) he advises the provision of more hospitals and the better training of medical men, and under heading (3) the segregation of the infectious, the institution of quarantine and the destruction of infected clothing are among the measures advocated. There are a few suggestions which will appear quaint to us to-day. "Chewing tobacco and other herbs should be used. Flowers should be introduced in sick-rooms." The introduction of flowers and herbs, especially in Law Courts where great distemper prevails, are among the suggestions made. It is still a custom to present the presiding judge at many of our courts with a bouquet—a remnant of the old measure for protection from infection.

Remarkably foreseeing as these proposed measures were, it is strange that the whole subject of public health in 1815 could be contained in seventeen small pages of a book.

The chapters on medical jurisprudence on the whole contain few statements which could not be incorporated with accuracy in a textbook issued to-day. But there are a few assertions made which would not be considered as holding good to-day. For instance under rape I doubt if this extract can be accepted as correct: "But the consummation of a rape, by which is meant a complete full, and entire coition which is made without any consent or permission of the woman, seems to be impossible unless some very extraordinary circumstances occur." Again, it is stated that if absolute rape is perpetrated pregnancy is unlikely. This is not in accordance with fact.

In speaking of abortion Farr makes the statement that there is no drug known which by itself will cause abortion. This is perfectly correct if one adds the words "without grave risk to the health or life of the mother."

The book concludes with a chapter by William Hunter on the uncertainty of the signs of murder in the case of bastard children. The distinguished author of this essay makes an eloquent plea for a more merciful treatment of women accused of infanticide of their illegitimate offspring, pointing out the necessity for much more careful and scientific examination of the dead child before deciding it has been killed and has not died naturally.

This little book, published first over 150 years ago, is remarkable in that almost all contained in it is in accordance with orthodox medical jurisprudence and public health to-day.

L A PARRY

The British Council is arranging a programme for Lieut-Gen. Kim Cheung, Dorn of the Army Medical College Shanghai, who is visiting Britain to see methods of undergraduate and postgraduate medical training in hospitals and universities, the medical organization of the British Army, and military medical training. He is also interested in elementary and secondary education. A graduate of the National Army Medical College, Peiping, and an M.D. of Berlin University, Lieut-Gen. Kim Cheung was Surgeon General of the Chinese Army for several years during the war, and a member of a mission to the U.S.A. to study medical education and training in 1947-8. During his two and a half months' stay in Britain he will visit Cambridge, Oxford, Edinburgh, Glasgow, and Liverpool.

## Correspondence

### Status of the Academic Worker

SIR—It is surprising that many medically qualified academic workers are not yet aware of the Full-Time Non-Professorial Medical Teachers, Laboratory or Research Workers Group of the British Medical Association. Short notices dealing with the proceedings of this group appear from time to time in the *Journal* and yet somehow fail to catch the eye of many of the Association's members working in laboratories.

It is particularly unfortunate that at this time of change and uncertainty so many should be unaware of the group that represents their interests. The need for such a body is overwhelming, especially for the more junior members at present occupying demonstratorships or equivalent posts. This class of worker, unless possessed of private means, seems to day to be in an almost impossible position. After spending some three years taking a high-class honours degree in natural sciences (in common with general science students), followed in some cases by a year of preliminary research, he proceeds with the usual three years' hospital training and a year in house posts. Then on returning to the academic sphere he realizes that the medical degree he once thought to be only an advantage is in reality a mixed blessing. His colleagues, who are not medically qualified, have four years' seniority in teaching and research experience. After a further five to ten years' work he finds that he is, under present conditions, unable to provide a reasonable household for his family or to educate his children in the way he desires. His misfortune is that often his outlook precludes any active steps to alter his conditions of service or reward. Whilst the Inter Departmental Committee puts forward recommendations dealing with the remuneration of practising consultants and specialists, and the NHS (whatever its failings may be) deals with the remuneration of the general practitioner, the medically qualified academic worker is apparently forgotten.

Unless some change in conditions occurs it seems inevitable that this valuable member of the community will disappear. Present workers will probably be unwilling to change their mode of existence, but lack of replacement will lead to extinction of this branch of the profession. If an academic career is planned, a medical degree will be regarded as an unnecessary refinement. If a medical degree is obtained, the financial attractions of specialist or general practice will be too strong to resist. The medically qualified preclinical teacher will cease to exist. This is a very real and grave danger, and would seriously affect the standard of medical education in this country. At least a few medically qualified pathologists, physiologists, pharmacologists, biochemists, and anatomists are essential. The condition of survival of these teachers is largely dependent on their activities as a corporate body. For this reason I feel the lack of knowledge in academic circles concerning the existence of the only body of this kind—viz., the Full-Time Non-Professorial Group—is to be greatly deplored—I am, etc.

Cambridge

GEOFFREY W HARRIS

### Prevention of Venereal Disease

SIR—The latest Report of the Ministry of Health (for the year ended March 31, 1946) has to acknowledge an alarming setback in venereal disease that has dismayed everyone who understands its significance. The Report of the Ministry says "During the year 1945 the incidence of syphilis and gonorrhoea increased appreciably." This has happened after large sums of public money have been spent by the Government, through the Central Council for Health Education, in telling the public of the dangers of VD, and in trying to conquer VD by fear and persuasion, coupled with treatment after the illness has developed. The public has not been allowed to learn the vitally important fact that a great deal of VD is easily prevented. This is a scientific fact and it has been known for forty years.

During the great wars the fighting services all over the world, owing mainly to the persistent efforts of this Society, were protected (more or less, according to the enthusiasm of the

officer-in-charge) against these diseases by the preventive measures we have advocated for thirty years. But the civilian population all the time has been kept in ignorance, and so VD is on the increase.

The statement by the Government-appointed Trevethin Committee (1922) that "properly and promptly applied disinfection would almost certainly prove effectual" has been ignored, and up to the present no Government has had the courage to translate these findings into action. It has been left to us, a voluntarily supported society, to work alone. And not only do we have to fight disease but very often violent prejudice as well.

Our policy is threefold: (1) to educate the public with regard to the fact that VD can be prevented by simple, scientific measures; (2) to supply all interested persons with details of such measures; (3) to secure the necessary alteration of the law to enable preventive materials to be sold together with instructions. This Society cordially supports any and every method whereby VD can be combated, but it is confident that VD will be eliminated only by practical prevention. Without practical prevention any campaign against VD is doomed to failure.

About 100,000 men and women sufferers from VD will be treated at clinics this year, and there will be a great number of infected persons who will not go to clinics. We are planning a great campaign to set the people free from VD and from the prejudiced tyranny that has kept them in ignorance of the facts. The scope and magnitude of this great attack depends upon the support we receive from the profession and from the general public. Let us show you how you can help—I am, etc.,

### A Tribute to Former Officers of the LCC

SIR—As an addendum to Sir Allen Dalcy's wholly admirable article on "The Health and Municipal Hospital Services of London" (July 3, p. 19), I should be grateful if you would allow me to pay my humble tribute to the truly magnificent services rendered to the LCC Hospital Service between 1930 and 1939 by the principal medical officers of those years, Dr William Brander and Dr H W Bruce (general hospitals), Dr J A H Brincker (special hospitals), and the late Miss Bannon CBE matron-in-chief. I should also like to add Dr W B Knobel who, working in close co-operation with the Supplies Department of the Council, was responsible for the building up and development of an extremely important section of the Hospital Service.

Not one of these ever received any public recognition of their great services to London—all the more reason therefore for their old chief to take this opportunity, when the LCC Hospital Service has come to an end, of placing on record the great debt of gratitude due to them by all Londoners—I am, etc.

London W 8

FREDERICK MENZIES

### Test of Death

SIR—The alteration in the contour of the pupil on pressing with the finger over the ciliary region of the eye, as mentioned by Dr G P Bletchley (June 26, p. 1257), depends on the intraocular pressure. In the normal eye this sign is present in life. It is more easily noticed in eyes with relatively low pressure, and is made use of by ophthalmic surgeons to provide evidence of the state of the intraocular pressure. It is less easy to detect if the pupil is small, but it is nevertheless present. If one eye is covered the pupil of the other dilates slightly, and the change of shape is more easily seen. As soon as the blood supply to the eye ceases, as in death, the intraocular pressure falls and the alteration in shape on pressure is then obvious and might be made use of as a "test of death," but it is hardly correct to state "that it is impossible to press the pupil out of its circular shape during life." It seems open to question whether such a test would be reliable in the kind of case in which a test of death is required—I am, etc.,

Edinburgh

H M TRAQUAIR

### Voluntary Euthanasia

SIR—Cardinal Griffin's outspoken condemnation of voluntary euthanasia at a service for delegates to the B.M.A. meeting at Cambridge held in the Roman Catholic church has received considerable notice in the Press. One of his grounds for condemnation was that "a doctor's duty is to save life and not to destroy it", and "if it were recognized as part of his duty to inflict death he would rightly deserve to lose any confidence that the public had ever placed in him" (I quote from a report in the *Manchester Guardian*). May I point out that doctors have many other duties besides saving life, also that under our Bill—the Voluntary Euthanasia Legalization Bill—introduced into the House of Lords by the late Lord Ponsonby, it is not proposed that any general practitioner should ever be called upon 'as part of his duty' to administer voluntary euthanasia. On the other hand it is expressly laid down that only a doctor who has obtained a special licence for the purpose may do so—I am, etc.,

Legalization Society

### B.C.G. Vaccination

SIR—In a recent letter Prof. G. S. Wilson (June 26, p. 1254) pleaded for "a properly controlled investigation into the value of B.C.G. vaccination under English conditions. I thoroughly agree with him and believe that this would be a most valuable piece of research."

But he also suggests that the B.C.G. should not be released for use in this country until this experiment which he has estimated may take from five to ten years<sup>1</sup> is concluded. Though I made a similar suggestion myself in 1934, much has happened since then, and I do not now see on what grounds we can continue to be one of the few remaining countries in the world in which this vaccine is not obtainable.

Well over three million children have been vaccinated over the last 26 years, and it is now generally conceded that the vaccine is safe, moreover at the recent Congress International du B.C.G. in Paris, at which thirty-five countries were represented and over eighty papers read, no instance was reported in which the B.C.G. failed to produce immunity. As I have shown elsewhere,<sup>2</sup> B.C.G. vaccination can be added at little expense to our organization for fighting tuberculosis without in any way interfering with the existing scheme.

It has been pointed out that in this country there is a tendency to a decline in the incidence of tuberculosis without the use of B.C.G., paradoxically this very decline is resulting in an increasing number of young adults leaving school and entering factories with a negative Mantoux. Need they, together with the children who are forced to remain in contact with tuberculosis through the present lack of institutional accommodation await the result of the British experiment before receiving the benefit, however statistically unproven, of B.C.G. vaccination?—I am, etc.,

Henley-on-Thames

### Prevention of Dust Diseases of the Lung

SIR—After perusing recent articles on pneumoconiosis, anthracosis, and affections of the lungs due to the inhalation of dust and irritant particles (May 29, p. 1015, June 5, pp. 1065 and 1087), one is again lost in wonder that no mention is made of the simple and sure means of prevention and protection—that is the use of a small light pad over the nose and mouth, as worn by nurses in the operating theatre, children's wards, etc. The pads, of course, are merely some six folds of butter muslin or gauze, with tapes to tie behind the head, and could be provided in unlimited quantities to be discarded after use. Grit and dust particles cannot be inhaled through such a protection, and all workers under dusty conditions could be assured that no harmful results could possibly occur if so protected. The application to coal-miners is, of course, particularly significant at the present time.

By all means let us diminish or eliminate as much as possible the creation of dust and grit in trade processes, mining, etc., but surely real prevention of anthracosis, silicosis, or any form of pneumoconiosis can be obtained only by providing any exposed worker with a simple shield which will prevent any dust particles from ever gaining access to his respiratory system. The Director of the Pneumoconiosis Research Unit states that pneumoconiosis is a preventable disease and calls for imperative administrative action. How very right! But is it too much to hope that such action might be directed towards preventing the condition arising by the simple expedient suggested rather than setting up a costly organization to deal with the crippling and often fatal, after-effects?—I am, etc.,

Senior Tuberculosis Officer

### Gastric Herpes Zoster

SIR—I read with interest the two cases of so-called gastric herpes zoster reported by Dr. R. V. Stone (May 8, p. 882) and by Dr. P. E. Fitzpatrick (June 19, p. 1206). However, I should like to point out that neither the epigastric parietes nor the stomach itself is innervated by fibres from T 9 and 10. There is still no unanimity on abdominal topography, and I strongly advise the acceptance of the recommendations of Brown and Smith.<sup>1</sup> They advocate a modified Glisson's method of subdividing the abdomen. If this were used, then it is easy to map out the cutaneous innervation. The epigastrium is innervated by fibres from T 5, 6 and 7, the umbilical region by fibres from T 8, 9 and 10 and the hypogastrium by fibres from T 11, 12 and L 1. Brown and Smith have shown that the umbilicus is an unreliable landmark and should never be used as such.

Brown has put forward the interesting theory that many organs (e.g. diaphragm, appendix, and testis) receive their nerve supply before migration and that once innervation is established future migration makes no difference to localization of pain. I believe that this also applies to the whole of the alimentary canal. In this case the stomach develops well cranially, probably opposite somites corresponding to T 5, 6 and 7, small intestine opposite T 8, 9 and 10 and large intestine opposite T 11 and 12 and L 1. One would expect pain from an ulcer at the lower end of the oesophagus to be "felt" in the distribution of T 4. Clinical observation shows this to be the case—the patient always pointing to an area in the midline above the xiphisternal joint. Similarly pain from a gastric ulcer is felt high in the epigastrium and duodenal ulcer low in the epigastrium (corresponding to T 5, 6 and 7). Small intestine pain is felt in the umbilical region (corresponding to T 8, 9, and 10)—the appendix corresponds to T 10 low in the umbilical region. Large intestine pain is felt in the hypogastrium (corresponding to T 11 and 12, and L 1).

It should be noted that the early pain is always felt in the midline—the early embryonic position. Accurately localized abdominal pain other than in the midline is always secondary to peritoneal peritoneal irritation—e.g. appendix pain in the right ilio fossa and gall bladder pain at the 9th rib—and is much later in onset—I am, etc.

### Pain in Childbirth

SIR—The correspondence regarding pain in childbirth indicates that too little is known of the value for the emotional life of women of the experience of childbirth. My work for the Sheffield Marriage Guidance Council brings me in touch with cases where chronic unhappiness, constant ill health and marriage breakdown are clearly due in part to the wife's unsatisfactory sexual achievement. This is frequently associated with failure to achieve orgasm during intercourse, but this is in fact so common that the problem is not as simple as it may have appeared.

Woman's sexual satisfaction is not necessarily achieved only during intercourse, but also during the whole sequence—pregnancy, parturition, and lactation—which brings a development

that is not only biological but has the highest personal qualities. It is therefore not so much a question of the experience of pain only, but of the experience of a profound and severe sensation. The anaesthetized Kaffir buck which has been alluded to felt nothing at all and naturally found difficulty in understanding the situation. The human mother can be persuaded that the babe is indeed the one she has been bearing but even then, unless labour has been long and difficult, she has at least a greater pleasure in being conscious and co-operative during what is after all a woman's major creative activity—the creation of another life.

Dr G. Dick Read's suggestion (June 26, p. 1256) that childbirth can be a wholly positive, responsible achievement should do much to redress the present tendency in some sections of the population to under-value the experiences of childbirth and the effort to overstress the experience—sometimes disappointing—of intercourse, and to postpone conception indefinitely. Naturally there is a widespread reaction from the ignorance and proliferation of past generations and some couples find it wise to achieve a good married relationship before pregnancy but women need to find a balance and a new integration between their erotic and maternal sexual activity and the wider emotional and intellectual life of which they are capable. The over-possessive mother, of whom we are so afraid, may be compensating by a distortion of mother-love for an inadequate experience, at the proper stages of the sexual possibilities of marriage and motherhood. I know several cases where wives have more desire and a more successful relationship to their husbands after childbirth undertaken with Dr G. Dick Read's routine. I would not decry wholesale the use of anaesthetics in labour, but the case has been made for a reconsideration of this question.

The abandonment of moral standards and the appalling breakdown rate of marriages, with the resulting effects upon the health and happiness of the community, might well be checked by a higher value being set on woman's contribution to society. Economically and intellectually she has rightly achieved a position equal or nearly so to that of man but if her creative life lacks feminine development and expression not only she but our society as a whole will suffer distortion and frustration. Hence any contribution to our understanding of the experience of childbirth will be a help not only to obstetricians and psychiatrists—I am, etc.,

Sheffield

HELEN B. HERALOTS

SIR—I should like to thank Dr. Grantly Dick Read for his letter (June 26, p. 1256). I believe Dr. Read's approach to be the right one. Certainly his results are impressive and his technique should be investigated on an extensive scale.

In spite of the frightful scandals revealed in the 1937 maternity mortality report this country still steadfastly refuses to give our mothers proper attention. No serious attempt whatever is being made on a national scale to present motherhood to our girls as a wonderful experience and achievement. We are content that it shall remain a nightmare of horror for thousands of young women, and in this nightmare their spirit and their health is too often ruined—I am, etc.,

New Barnet, Herts

J. E. ELAM

### Lower-segment Caesarean Section

SIR—Mr. B. C. Murless has described in your columns (June 26, p. 1234) the ingenious instrument he has invented to help him in the extraction of the head from the lower uterine segment in caesarean section. When working without an assistant some such apparatus should prove exceedingly helpful. May I suggest to him the following manoeuvre when an assistant is available?

After the abdomen has been opened and the self-retaining retractor inserted, the operator puts both hands into the pelvis and elevates the head. His hands are then replaced by the assistant's left hand, which with the tips of the fingers (and with the wrist strongly dorsiflexed) keeps the head in the elevated position. The surgeon now incises the peritoneum in the line of the utero-vesical fold, sponges it down together with the bladder, and then cuts down on the head until the membranes are reached. These are picked up and cut with the scissors. The head immediately begins to present at the opening, and with a snick of the scissors in an

upward direction at either end of the wound sufficient room is available for the delivery of the head. While the incision is being made into the uterus the anaesthetist injects 1 mg. of ergometrine intravenously—I have entirely given up the use of "pitocin" for this purpose—and with the head directed into the wound the uterus does the rest.

The only occasion on which any awkwardness may arise is when the assistant has an insufficiently supple wrist but after a little practice a sufficient dexterity is quickly acquired—I am, etc.,

Torquay

B. VENN DUNN

### Aberrant Endometrial Tissue and Intussusception

SIR—Dr. E. M. Southern (June 19, p. 1178) reports my case of irreducible intussusception at the apex of which was found endometrial tissue. He concludes that the chronic intussusception probably gave rise to the stimulus which caused serosal metaplasia. I submit that the ectopic endometrial tissue caused the intussusception. Since the menarche at 14 years this patient, now 23, had vomited on the first day of each period which necessitated her spending this day in bed. Since I resected the affected portion of the intestine she has had normal periods, free from vomiting. The history of recurrent attacks of intussusception was only three months. Part of the section (I enclose a photomicrograph) shows blood in the

endometrial tubules. My view is that her vomiting and pain on the first day of each period were due to this menstruation into the ileum. During the three months before operation this had caused sufficient swelling to form the apex of an intussusception, at first spontaneously reducible, finally irreducible. The fact that she no longer has dysmenorrhoea implies that all ectopic endometrial tissue has been removed—I am, etc.,

G. C. DORLING

### Medical Photography

SIR—Having previously written to the *Journal* on the above subject I was interested in the letter by Dr. J. H. Twiston Davies (May 22, p. 1001). In the *Journal* of Oct. 20, 1945 (p. 548), Dr. S. Watson Smith wrote advocating the photographer-physician combination, and I agreed with him and gave some technical details of colour photography in the issue of Nov. 17, 1945 (p. 704), and also on the taking of colour photomicrographs with an ordinary camera in the *Journal* of Jan. 29, 1944 (p. 164).

During the past 22 years as a dermatologist I have done a good amount of clinical photography in this special branch. For the last nine years I have been converted to colour photography in particular, as it is undoubtedly the best medium on which to record skin cases. I know there are some snags and difficulties with colour work, but difficulties are made to be overcome, and when one remembers the early efforts at x-ray photography and compares them with the present products of that branch of medical photographic art, even on the 35 mm. mass radiography films now fairly popular, one must realize

that things have improved. I know that some dermatologists who have not been successful with colour photography say they would rather have a good black-and-white picture, but then the real answer should be that they ought not to have taken a bad colour one.

One of the present day troubles of acting as photographer-physician is that it is very difficult in these days of hard drudgery and work in dermatological out-patient departments (where often most of our best pictorial provender is provided) to find time to take any photographs. Hence, much as I dislike it, I have tried at different times to get a professional photographer to take photographs of a case for me. The result has always been most disappointing or a complete failure, even though the photographer has been a most highly qualified technical person. In my experience professional photographers are often somewhat fussy and pedantic, and more inclined to think of a studio portrait or picture than a clinical one. The latter may be taken solely to bring out some particular point—e.g., the burrow or acarus in scabies on the foot of an infant.

"Hospital photography departments are often an absurdity," as Dr Twiston Davies states. Furthermore, the so-called clinical camera is often an antique abomination and an anachronism totally unsuitable for its object. Usually it is a bulky half plate affair with a small aperture, poorish quality lens capable of only some prolonged exposures, and unable to reproduce true details in anything like reasonable time. Its bulkiness does not permit rapid change of position when taking a quickly moving object, and one would find it impossible to take such an object as an unruly child with eczema of the face, etc. It cannot conveniently be used anywhere in the hospital owing to its size, and is not suitable for use either at the bedside or in the out-patient department.

Having been somewhat destructive in my criticism, let me now offer some constructive ideas. For good clinical work I think a camera made on the combination of the ideas incorporated in either the "Leica" or "Contax" with the "Reflex Korolle" and provided with a good-quality lens capable of doing clinical work with an F 3.5 aperture would be valuable. It should be capable of taking a good detailed picture in artificial light using F 3.5 aperture at not more than one thirtieth of a second. If made on the above principle it should not be bulky or heavy in weight, and could readily be held in the hands if necessary for bedside work and also for taking photomicrographs in colour.

There are obvious advantages in using 35 mm film for clinical work, including convenient size, cheapness, and the fact that it is possible to get all varieties of film in this size. In the USA it is possible to get copies and enlargements in colour from 35 mm colour transparencies, and those I have seen are quite good, but owing to monetary difficulties in this country at present it is not feasible to get this done here. Perhaps later on it may be done, and in any case it is an accomplished fact.

With regard to a properly equipped photographic department in a hospital, there is always a certain amount of routine work that could be effectively carried out there, such as the taking of pictures of pathological post mortem specimens, photomicrographs of sections, copying, enlarging, and reducing prints and negatives, developing and printing, etc.

The other day, when I was at a certain hospital I was told the committee had sanctioned the purchase of photographic equipment up to £200 in all, and they thought this was an enormous sum for the purpose. I can assure them that this is not so. It might buy the very minimum required on the second hand market to start with but no more—I am etc.

Leicester

F A E SHICK

SIR,—The criticism of my remarks by Mr William Gissane (July 3, p 53) in no way alters my opinion for from long experience, but on much more modest lines, I found that medical photography tended to useless extravagance particularly when the enthusiast did not bear the cost. As we are told that some 5,000 prints "are confined to less than 2% of the patients we treat," are we to assume that the rate of progression indicated by the figures quoted will continue with expansion of the department until 100% are photographed? I cannot help but think that research workers would benefit by memorizing Hamlet's advice to the players. Even if all the "hoped for" results could be so achieved, it would be well at this time, before launching out into expansions of ancillary services, to remember that we have run through the American loan of £937,000,000 in 18 months, and further loans threaten seriously to lower the already very low standard of living.

Nothing would have pleased me more than to have received the co-operation which would have permitted me to feel that I had earned the credit Mr Gissane so generously bestowed

No one knows the practice in modern fracture practice better than he but I have repeatedly warned clinicians of the folly of taking unnecessary risks, which they do by purposely avoiding rather than seeking the co-operation of radiologists. It is regarded as negligence in the courts if the doctor has failed to have x-rays taken in cases of possible bone and joint injury, but it should be realized that an equally serious charge may be sustained if it is proved that the radiography was insufficient or showed evidence readily recognized by the expert which had been overlooked. It would not help matters to urge that the hospital had available a competent radiologist—I am, etc.

Edgbaston Birmingham

JAMES F BRAHNSFORD

### Surgery of the Heart

SIR—Everyone must be greatly interested in the newest approach to the surgery of the heart as detailed by Mr R C Brock (June 12 p 1121). His achievement at once reminds me of the foresight and vision of the late Sir Lauder Brunton (died 1916) who in 1902 wrote a "Preliminary note on the possibility of treating Mitral Stenosis by Surgical Methods" (*Lancet* 1902 I, 352).

It was some years afterwards I heard that physician speak on the idea of its possibilities. Had he been with us to day he would indeed have been fascinated and glad to know that some surgeons have come so near to attaining what he envisaged—I am, etc.,

Maldenhead

G GREY TURNER

### Slings Plaster Beds

SIR—I am enclosing details of an extremely simple and very efficient method of slinging plaster beds etc. It lends itself to a variety of uses and simplifies the nursing problems. It is cheap and the parts can be used again. Also an infinite

Uprights are 10 in x 12 in domestic shelf brackets obtainable at any ironmonger's.

variety of cross bracing and strengthening is possible, even after the patient is in occupation of the cast—I am etc.

London NW 4

ROBERT HUNT COOK

### Suggested Substitute for Talc

SIR—I have read with interest the three papers and your annotation (June 5, pp 1077, 1078, 1079 and 1090) on silicone granuloma produced by talc when used as a dusting powder for rubber gloves in surgical operations. May I suggest that a suitable substitute for talc might be light basic magnesium carbonate in which the particles have been coated with magnesium stearate? The fatty acid content of the magnesium carbonate is about 4%. By this means the physical characteristics of talc are largely reproduced—i.e. softness and slip. The apparent density is much lower than that of talc and therefore a smaller weight is required for dusting a given surface.

I do not think the magnesium carbonate would have any undesirable effect should any accidentally get into the wound but I am not sure about the small quantity of stearate. Alternatively, plain light magnesium carbonate might be sufficient for the purpose. Both these products are used in the rubber industry as dusting powders and are readily available—I am etc.

Washington Chemical Co. Ltd  
Washington Co. Durham

J S F GARD

### Acute Deficiency Diseases

SIR—In the pamphlet issued by the Nutrition Subcommittee of the Colonial Medical Research Committee on the treatment of acute deficiency diseases, referred to in a recent issue (June 26, p. 1247), there appear to be some important omissions.

1 Nutritional oedema is not mentioned yet experiences recorded by medical officers who were P.O.W.s in the Far East show that not only was this more common there than wet beri-beri but had been frequently mistaken for that condition.

2 Besides Wernicke's encephalopathy due to vitamin B<sub>1</sub> deficiency there is the pellagra encephalopathic syndrome described by Jolliffe and others which does not respond to vitamin B<sub>1</sub>, but to high doses of nicotinic acid.

3 No mention is made of central cord syndromes, which may or may not be associated with nutritional retrobulbar neuritis. Incidentally may one call attention here to the morbid histology of these conditions illustrated by H. H. Scott in his fatal cases of central neuritis (*Ann trop Med Parasit* 1918, 12, 109)?

An impression remains also that some of these deficiency states have been rather over-simplified, for in spite of our advances in knowledge some of the causes are still largely unknown even if others can be excluded—I am, etc.,

Cheltenham

D. FITZGERALD MOORE

### Inquests and the Press

SIR—Were it not a tragic sign of the times, it would be comic to see the British Medical Association becoming permeated with the most pernicious of all socialist ideas—that man must be guided, directed, bullied, exhorted, and, above all, protected from the hard world.

I refer to the proposal to seek a limitation on the reporting of suicide cases on the grounds that others are tempted to do likewise, and I write not as a journalist wishing to report all the details for the sake of a "story," but in defence of the right of the responsible citizen to a newspaper which mirrors life in full, and not just so much of it as his legislators and their officials, and it now seems his medical advisers, think is good for him.

Surely it is their preoccupation with mental illness that has made these members of such a body as the B.M.A. subscribe to the current doctrine that the world must be made safe for the weak-headed. Must they not on reflection realize that the responsibility of the individual is the foundation on which rests the survival of mankind?—I am, etc.,

Sheffield Telegraph

TUDOR I. THOMAS,  
Chief Sub-editor

### "Young" Doctors

SIR—I and my contemporaries have to thank you for publishing Dr. Hopkins's pathetically true letter (June 26, p. 1258). What he complains of, in brief, is the premium of protracted penuriousness that continues to be placed on academic and clinical self-improvement, the result of the scandalous wages paid for "superior" appointments. The persistence of such a state of affairs is obviously the economic result of blind, thoughtless competition of the fierce present-day type. The shameful, unexaggerated truth of Dr. Hopkins's statements is not in doubt from any quarter. If we, his fellow-sufferers, cannot unite in drawing the forceful, fecund attention of the profession and the public to this matter, we have only ourselves to blame—I am, etc.,

London N.W.3

A. GUEDATARIAN

### The Homosexual in the Courts

SIR—The letter from Dr. Eric Coplans (July 3, p. 53) properly draws attention to a state of affairs which many of us regard as urgently needing full and frank discussion between doctor and lawyer. The situation such as Dr. Coplans describes is no doubt distressing. I would submit that the situation of the homosexual who seeks advice on account of his homosexuality and recognizes that not only is he not as others but that a way of life which is to him desirable is barred to him

is in an even worse position. Such people suffer from a distress of mind which is profound and yet may in no way be aggravated by any threat of punishment.

Study of these cases over a number of years leads me to suppose that there are certainly a variety of groups, including those in whom the activity is prosecuted in a manner suggesting depravity, those in whom the innate deviation has been successfully controlled until some additional factor breaks down that control, those in whom the innate deviation is recognized and deplored, and finally those in whom the innate deviation is present but not recognized or at a conscious level.

There can be few of us who would not agree that assaults whether heterosexual or homosexual, upon children should be punishable, but whether it should now be recognized that in homosexual as in heterosexual "assaults" an "age of consent" should obtain is a matter surely for careful debate. The law has been accused of lagging behind public opinion, but recent events in both Houses have surely shown that careful study of medico-legal questions from all angles is necessary before any change in the existing penal code be considered—I am, etc.

Turton Somerset

### Biography of Sir Bernard Spilsbury

SIR—I am collecting material for a biography of my father the late Sir Bernard Spilsbury, and would be most grateful to anyone who can supply any information which would be helpful. Any documents or photographs will be copied and returned immediately—I am, etc.,

8 Eton Hall, Eton College Road,  
London N.W.3

EVELYN STEELE

### A Medical Reply to the Minister

SIR—The Minister (July 3 p. 1) sends a pleasant message to the profession on the eve of inaugurating the new Service. He lives on a plane remote from the hard and cruel facts of human suffering. His views are provocative.

When during the past year the Minister and profession have been joined in battle, for him to say that the Act "has not had an altogether trouble-free gestation" is a travesty of truth. Nor is the money factor irrelevant to the doctor-patient relationship, though the manner of its transfer may need adjustment.

He recognizes the stigma of "panel doctoring," but his Act offers to extend this degraded standard of practice to the whole nation. The conditions of the panel which prevent good work are aggravated by his legislation. Doctors are already over-worked and will be no more numerous but their surgeries more crowded. The undertaking is novel in taxing all classes but there will still be "two grade service under the Act," because like the Minister, many citizens disapprove of panel doctoring and, where able, will pay extra to obtain the advantages of a private doctor. This is as regrettable as it is inevitable. Sir Lionel Whitby cheers us by his erudite address following the Minister's message in the *B.M.J.* by impressive figures on the cost of elaborate modern medical services, prohibitive for the individual but now to be borne by the State. This is tantalizing as the benefits are not there to be paid for but merely a place on ignominious waiting lists. He quotes interesting historical precedents for State control of medicine, but omits mention of the disappointment that has followed recent efforts in other countries.

The profession in the last decade expressed its whole-hearted desire for a comprehensive national service, but between that great conception and the creation thereof we know by our knowledge and experience of health problems that a lengthy pregnancy must intervene. Had we been consulted in planning reformation the nation would have been spared the disgrace of last week's abortion. An "ambitious adventure" need not be precipitate. Some prominent doctors claim that the B.M.A. has in recent weeks gained "a victory," but this is a misnomer for removing a few ugly excrescences off a sham castle.

Let us go forward undaunted with the Minister to build a national health service, but it must be founded on truth and proceed by stages—I am, etc.

Bristol

A. WILFRID ADAMS

### Safeguards in Service

SIR,—As a member of the B M A who has been compelled, like many others, to join the National Health Service under economic pressure, I would like to ask our leaders the following questions

1 As we have now surrendered on all the points for which we fought, exactly what legal safeguards has the B M A secured for the doctor entering the Service against unfair dismissal or victimization on ideological or other grounds, seeing that we have surrendered the right of appeal to law against the decisions of an arbitrary authority? An Amending Act to prevent the institution of a salaried State service is obviously no sort of protection against injustice of this kind

2 In the event of one of its members being the victim of injustice and tyranny of this sort, exactly what action would the Association be prepared to take on his behalf?

3 Exactly what concessions (apart from the so called Amending Act) has the B M A secured for us from the Minister in return for the surrender of our fundamental rights as free men?

4 What grounds has the B M A for believing that, now we have surrendered completely, the politicians intend to carry out their obligations towards the profession in an honourable manner? For example, what guarantee have we from the Minister that the proposed capitation fee will under no circumstances be ever reduced?

5 What steps the leaders of the Association are taking to secure for our profession the same rights and privileges as those of other workers—i.e., the 48-hour week, holidays with pay, guaranteed full employment, and so on

Would the leaders of the Association please issue a clear statement in answer to these questions?—I am, etc

London S E 6

### Film Propaganda and the NHS

SIR—Amidst the deluge of propaganda which the authorities deem necessary to herald the new Service, I wish to deplore the misrepresentation of medical practice and the general practitioner in the film features showing in the cinemas at present. The latest Ministry of Information effort shown in the local cinema suggests that the general practitioner is ineffectual and obsolescent—a purveyor of doubtful medicines, inadequate in the simplest diagnosis, quite ignorant of modern medicine and, in fact, a menace to the sick. But after July 5 public toleration of this state of affairs will be relieved by the large army of specialists waiting to rectify his ignorance and treat the ill; their misguided colleagues have left unrecognized for so long.

This is the content of a film shown to a vast section of the community, readily influenced by visual impressions, and which until recently had a certain loyalty to and faith in the family doctor. It seems an inopportune moment for an attempt on the integrity of general practice—that “backbone of the profession” we are so often reminded of—at a time when confidence is so badly needed in it. Can we afford to ignore the spirit of this indecate publicity, or is it part of a campaign to relegate general practice to the level of that suggested in the film—condoned by whatever medical advice the producer necessarily enlisted? This is yet another example of Ministerial publicity in keeping with the “widow of the roads” poster, and made so much worse by the irresponsibility of the members of the profession who so encourage such nonsense.—I am, etc,

Rugeley Staffs

S DILLON

### Professional Secrecy

SIR—In the debate in the Northern Ireland Parliament on June 23 on a motion to annul Health Service regulations, Mr S T Irwin, F.R.C.S., M.P., said in relation to professional secrecy between doctor and patient, “In regard to records, I quite agree with the Minister that there has been a lot of rubbish talked about that point”, and again, “I should see no objection whatsoever to any record, even a full record, with the patient's name, being sent to the Ministry if they so desire” (*NI Hansard* Vol 32, No 36)

Mr Irwin may have voiced the opinion of the consultants, though I do not think so, but he certainly did not voice the opinion of the G.P., nor, I think, that of the great majority of the public and it is decidedly interesting to speculate that while these deplorable sentiments were in course of utterance Sir Ernest Graham-Little may have been writing the admirable letter published in your issue of June 26 (p 1259) which so adequately refutes them—I am, etc,

Belfast

W LYLE

### The Part-time Consultant

SIR—Mr G Lowe and Dr T N Rudd (July 3, p 24) have produced a most interesting and excellent defence (if indeed one was needed) of the part-time consultant. I was a little disappointed to see no mention of what may well be regarded as the point on which this method of specializing is most open to criticism.

The part-time surgeon operating on one of his own cases becomes the sole executor of that patient's fate. Of course this might also be applied to almost every contact made by a G.P. with his patients, but operative work is on a different footing in that the risk of a patient's life being made or marred—or even lost—is rather more formidable. The full-time specialist sees the patient at the behest of the family doctor, he decides to operate, and the G.P., seeing the outcome is in a position to vet the surgeon's work. If he is not happy about it he calls someone else next time. The part-timer operating on his own cases has no one to call a halt, for anyone with experience of the handling of patients and their relatives knows them to be very bad judges of professional merit. As often as not the patients one has done most for are quite ungrateful, while an unexpected death may well be met with most glowing tributes from the relatives. Certainly one's professional standard could not be expected to rise to any great heights if such a capricious tribute—however much “at close quarters”—is accepted by the part-timer. I must confess that I can find no answer to this criticism, unless the part time consultant refrains from providing specialist treatment for patients who have come to him primarily in his capacity as a G.P.—I am, etc,

Redhill Surrey

### Remuneration of Consultants

SIR—Apart from the “prizes” suggestion no one will quarrel with the Spens Report on the remuneration of future consultants and specialists from their (consultant) infancy to their majority, but it appears that no recommendations have been made for present established consultants nor is there any differentiation between the senior man, in charge of beds and responsible for a team (in accordance with modern concepts of specialization) and the junior members of that team, with less responsibility. I submit that present senior consultants should qualify now for the maximum salary and “prize” and that the basic salary be paid to the assistant surgeons in his team, and that some method other than the “prize” should be evolved gradually to increase the assistant surgeon's salary until he becomes senior. In this way the senior surgeon would have his experience, training, and controlling of his team suitably rewarded, and would receive approximately the same amount as the general practitioner who is undertaking the training of an assistant with the maximum list—e.g., general practitioner with assistant and list of 6 400 £5,760, senior consultant basic salary £2,500, plus maximum prize, £5,000—I am, etc,

Middlesbrough

D C DICKSON

### Remuneration of Teachers

SIR—Your correspondent, Professor Samson Wright (July 3 p 47), discusses the discrepancy between the salaries of specialists in the medical profession and of teachers of medical students. He is rightly concerned that low salaries should not drive able men away from teaching.

This issue has wider aspects than those already raised and they must be taken into account when the future of medical teaching is being considered. Professor Wright mentions specifically anatomists, physiologists and biochemists, he implies that their remuneration is inadequate. Many, probably most of them, are university teachers. But medical students in

the preclinical stage are also taught (and, we hope influenced in the way Professor Wright desires) by chemists and physicists who are also university teachers. They too are recruited from "young idealists," and, if not subject to the temptations of the salaries offered by the National Health Scheme they could readily command higher salaries outside teaching than those which they receive from the universities.

It would therefore hardly be possible to increase the remuneration of teachers in one science department of a university without doing so in all others. It will readily be seen that similarly there could be no differentiation between the science faculties and the arts faculties. Thus a consideration of the conditions of service in teaching departments of medical schools must ultimately lead to a consideration of the whole of university teaching. Many of us in the universities would welcome this. My immediate point, however, is to suggest that medical teaching cannot be considered apart from university teaching as a whole—I am, etc.,

University College Hull

J J KIPLING

### Remuneration of Research Workers

SIR—Professor Samson Wright (July 3, p 47) has drawn attention in a striking manner to the contrast between the present remuneration of teachers of the basic medical sciences and that proposed for consultants and specialists in the Spens Report. It cannot be denied that the consequences he foresees if the conditions of service in teaching departments are not urgently reconsidered, are not unlikely to be fulfilled. I would like to point out that the contrast applies with equal force to whole-time medical research workers, whether they work in the universities or in research institutions, and more or less irrespective of their employers (except for a few industrial concerns). Medical research also may cease in the future to draw its share of the ablest medical graduates as it has in the past.

The contrast is of course not new, but there are two novel features in the present situation. The first is that the salaries proposed for consultants have been given wide publicity and the disparity is now clear to many people rather than to a few only. The second is that the conditions of service under the National Health Service are likely to remove a number of factors, such as the worries of building up a practice and of collecting fees, which in the past have decided able persons in favour of a career in teaching or research rather than in consultant practice. These two reasons apart from any considerations of proper rewards for service to the community, make a reconsideration of the position of medical teachers and research workers particularly urgent.

The problem does not end with medically qualified persons however. The possession of a medical degree may well affect the position attained by a teacher or research worker in his line of work, but it does not affect the ability or value of scientists without medical qualifications who are already doing good work in these fields. They will have to be treated equally with their medical colleagues. How far beyond medicine the repercussions may extend is a matter requiring much clear thinking and one to which the Association of Scientific Workers is giving considerable attention—I am, etc.,

ROY INNES

General Secretary

Association of Scientific Workers

London W1

### Medical Records

SIR—Now that most general practitioners are committed to practising under the new Health Act they will be supplied with large numbers of medical record envelopes, not only for actual patients needing treatment, but for all others who are not patients but have registered with them. In most cases these will amount to some thousands of bulky record cards and I trust all necessary steps will be taken to induce the Ministry of Health to supply us with suitable cabinets to house these cards satisfactorily. Clerks in Government offices are not expected to supply filing-cabinets for the cards they work with, and there is no reason why an exception should be made in the case of the medical profession—I am, etc.,

Slough Bucks

H TUDOR EDMUNDS

### Post Office Medical Officers and NHS

SIR—While one may sympathize with P.O.M.O.s in their loss of income consequent on the introduction of the NHS the terms "anomaly" and "injustice" can hardly be applied to a part of the Act which extends the right of free choice of doctor to considerable numbers of the adult community who have hitherto been denied this privilege. On the contrary, many P.O. employees (and doctors) may feel that this is one of the few anomalies and injustices which the Act will remedy.

It would be a serious mistake for the B.M.A. to ask for a restoration of the *status quo* (and presumably that is the only action they could take in the matter), since any request that a certain section of the community be denied free choice of doctor could be interpreted as a move towards that type of service which permits "direction" of the patient and disallows the doctor his right of refusal—I am, etc.,

Cookridge Yorks

CLIFFORD T ROBERTS

### Chemists' Working Hours

SIR—Dr M Mundy (June 19, p 1208) has given prominence to the fact that pharmacies are not open at a late hour to serve patients with urgent medicines, and he has stressed the efforts which he made to remedy this position when a member of the Middlesex Insurance Committee. On behalf of the committee of the Harrow Branch of the Pharmaceutical Society, which represents all sections of pharmacy in this area of Middlesex, I can assure Dr Mundy that the problem which he discusses is of no real significance. Some of our members live over their pharmacies, others have informed the police when and where they are available should the need arise, but all of them rightly resent an extension of their working hours for no apparent purpose. In a few instances cases have come to our notice where so called "urgent" prescriptions were issued two or three days previously, and an analysis of 151 prescriptions dispensed after closing hours over a period of 15 months showed only three forms which were marked "urgent" by the physician—I am, etc.,

H W TOMSKI

Hon. Secretary

Pharmaceutical Society (Harrow Branch)

Pinx Middlesex

### POINTS FROM LETTERS

#### Pain in Childbirth

Dr H M DENHOLM-YOUNG (Farningham Kent) writes. Several young mothers have told me that at the moment of delivery they felt no pain or discomfort, but a physical sensation of ecstatic pleasure. We know that delivery often means the utmost agony and an anaesthetic must surely be at hand, but if a woman is experiencing pleasure and refuses anaesthesia at the last moment it can only be unconscious jealousy on our part if we insist on giving it. May it be that our tenacious belief in the agony of birth is a desire that the mother should pay for possessing a child? One notices frequent unintentional cruelty by doctors, nurses, and teachers towards mother and child, expressed in possessiveness, bossiness, sneering at mother love, and devious excuses to separate mother and child in hospital and in school. We should always be aware and wary of this in ourselves.

#### Staircases and Ceilings

Dr RICHARD BELL (Haydon Bridge, Northumberland) writes. In modern times public health authorities have steadfastly directed that ceilings should be eight-and-a-half feet from the floor. The economic factor has always limited the size of rooms. From this it follows that staircases in modern houses are always too steep. This fact becomes more strongly impressed on one as middle age approaches.

There is absolutely no reason whatever why ceilings should not be lower and the floor space of rooms greater, if only one could break with the tyranny of custom. Then could the aged climb gently to their bedrooms.

#### Vaccination

Mr W K FITCH (London, WC) writes. I was interested in Surgeon Commander Smith's warning (July 3, p 54) that immunity to smallpox is not necessarily shown by the failure of vaccination "to take". One of my sons joined the Merchant Navy in 1942. His first voyage was to India, and at the first port of call he, another cadet, and several of the ship's officers were vaccinated. In no instance did it "take". According to the master of the ship it wasn't supposed to "take," for what did my son think would happen if everyone on board went sick with a sore arm? Needless to say, on his return to the UK he was immediately vaccinated, and there was no doubt that it "took".

## Obituary

Dr JAMES THOMAS MOORE GIFFEN died at his home near Chester on March 11 at the age of 84. Of Ulster stock, Dr Giffen was born and brought up in Co Antrim. He studied medicine at Glasgow University, and qualified in 1887. In 1892 he took the FRCSEd. Immediately after qualifying he served as surgeon to the Cunard Line before settling in Chester, where he continued to practise until his retirement in 1924. During the first world war he acted as surgeon to the Red Cross Hospital at Hoole Bank, where he did much useful work. Apart from this his professional work was entirely in general practice. He was for many years one of the leading and most popular doctors in Chester, and his name is still revered and spoken of with affection by his old patients. An enthusiastic fisherman and keen naturalist, the earlier years of Dr Giffen's long retirement were largely occupied in fishing and country rambles. Latterly, debarred from these occupations by advancing years and failing health, his time was mainly spent in serious reading. To the last he kept abreast of advances in medicine. From 1890 he was an active member of the British Medical Association, and in 1929-30 was chairman of the Chester Division. His honorary membership after fifty years was a source of much gratification to him. He was predeceased in 1946 by his wife, formerly Miss Bretherton, of Crabwall Hall, Chester. A devoted couple, they left no family.

Dr THOMAS ADRIAN GREENE, one of the leaders of Irish psychiatry during the first forty years of this century, died at his home at Killyleagh, Co Down, on June 26. Dr Greene, who came of landed stock in the west of Ireland, qualified in 1894, and first entered the mental hospital service as assistant medical officer to Ennis Mental Hospital. In 1909 he was promoted, at a comparatively early age, and became superintendent of Carlow Mental Hospital, a post which he held until his retirement in 1938. Dr Greene's contribution to psychiatry was essentially in the realm of administration, and throughout his active career he was always many years ahead of his colleagues. Carlow Mental Hospital, with its beautifully laid out grounds and gardens—Greene was an expert gardener—and its pleasantly decorated wards, was always the show-place of provincial mental hospitals. Here Greene instituted occupational therapy and the wide use of parole long before either of these systems was generally adopted. The Royal Medico-Psychological Association fully recognized Greene's contribution to psychiatry, and it was a keen disappointment to many of his colleagues that he felt obliged, purely for health reasons, to decline the highest honour which the association could bestow upon him. His great gifts of hospitality would undoubtedly have made his presidential year a memorable one. In the Irish division of the R M P A Greene was for many years an outstanding personality, and his chairmanship is still vividly remembered. His mental dexterity, ready wit, and somewhat unorthodox approach to what appeared to be difficult problems made each meeting at which he presided a mental tonic. Greene was a man of imposing presence. Well over six feet in height, and built in proportion, his physical dominance was matched by a mental dominance that to strangers was almost overwhelming. In manner he could be extremely brusque, especially if he detected any sham or pose, but this only made his word of praise, which he often gave generously to juniors, all the more appreciated. Even in retirement at his beautiful home in Co Down, Dr Greene's services were largely availed of, especially during the war years, when he gave freely of his time and energy to the training of ARP personnel and to the Red Cross Nursing Association. To those intimate friends who realized his frail state of health this effort takes on a new meaning. The sympathy of all who knew Dr Greene will be extended to his widow and his daughter.—R T

By the sudden and unexpected death of Mr S L JACKSON on July 1 the firm of H K Lewis and Co loses one of its directors, and Mr H L Jackson, chairman for over thirty years, his only son. Mr S L Jackson had many friends in the medical profession, and through his work for the Booksellers' Association was well known to many publishers as well as to booksellers. He served during the 1914-18 war in the West Yorkshire Regiment, and was acting captain at the time of his capture. He returned to the company early in 1919. He was in his fifty second year.

## Medico-Legal

### NULLITY DECREE ON BLOOD-GROUP EVIDENCE

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

Blood grouping has not figured very prominently in matrimonial cases. Its chief field of legal usefulness is in cases in which a woman asks magistrates for an affiliation order on the ground that a named man is the father of her illegitimate child and the man denies paternity. In such a case a blood group test will sometimes, if the man is really innocent, exclude him. The principle, broadly, is that the characters which determine a person's blood group are inherited as Mendelian dominants and therefore every character which a child possesses must have come from one of his parents. Ergo, if a child has a particular blood group which is not accounted for either by his mother or by the man who is said to be his father, another man must be looked for. There have been divorce cases in which a husband has won a decree by blood-group evidence which proved that a child borne by the wife could not have been his, and in at least one most interesting case a husband, summoned before the magistrate for failure to maintain his wife, has accused her of adultery on the basis of a test which excluded his paternity. In that case Mr Claud Mullins took the bold step of going against a report by Dr David Harley, although he was in general very receptive of scientific evidence and appreciated it with great understanding. In the end the parties were reconciled and the husband accepted the child as his own, and, let us hope, they lived happily ever after, but the champions of blood-grouping evidence, particularly in the United States, have never really forgiven either this *Journal* or its correspondent for agreeing with Mr Mullins over that particular case.<sup>1</sup>

A recent nullity case was decided largely on blood-group evidence. By Herbert's Act—the Matrimonial Causes Act, 1937, Sect 7 (1)—it was made a ground for a nullity decree that the wife was pregnant by another man at the time of celebration of the marriage if the husband did not know of the fact. In this case<sup>2</sup> the husband said that he had intercourse with the wife before marriage. This took place in June, 1945 and he married her in August, a full-term child was born in January 1946. Blood-group tests (done, of course, with the consent of the wife) showed that the child's blood group was A but both spouses were in group O, and therefore the husband could not be the father. Lord Merriman, president of the Divorce Division, granted a decree on this evidence corroborated by other facts.

There was a similar case<sup>3</sup> in 1942 when a decree of nullity was granted to a young officer whose blood group was OM, while that of his wife was BM, and of her child ABN. In expert hands the tests are for all practical purposes infallible, and it is a pity that lack of knowledge and suitable legislation has prevented their extended use in England. In many other countries the courts have for years been only too glad of their help in a very difficult class of cases.

## The Services

Lieutenant John McLenachan, R A M C, has been awarded the George Medal in recognition of gallant conduct in carrying out hazardous work in a very brave manner.

Major-General Sir Ernest M Cowell, K B E, C B, D S O, T D, K H S, has been appointed Honorary Colonel 44 (Home Counties) Infantry Division, R A M C, T A.

The following appointment and mentions in dispatches have been announced in recognition of distinguished services in Palestine.

O B E (*Military Division*)—Acting Wing Commander R A Fleming, R A F V R.

Mentioned in Dispatches—Acting Group Captain D A Wilson, R A F, Squadron Leader B R Little, R A F V R.

## Universities and Colleges

### UNIVERSITY OF CAMBRIDGE

The honorary degree of D.L. is to be conferred on Thomas Benjamin Davie, M.D., F.R.C.P., Principal and Vice-Chancellor of the University of Cape Town.

On June 23 the degrees of M.B., B.Chir. were conferred, by proxy, on D.J. Morton.

D. Girdner, D.M., and G.K. Harrison, M.D., have been recognized as Lecturers in the Faculty of Medicine.

### UNIVERSITY OF LONDON

John Leonard D. Silva, D.Sc., Ph.D., M.B., B.S., M.R.C.P., has been appointed to the University Chair of Physiology tenable at London Hospital Medical College, from Oct. 1.

Charles Horace Gray, M.Sc., M.B., B.S., A.R.C.S., F.R.I.C., has been appointed to the University Chair of Chemical Pathology tenable at King's College Hospital Medical School, from April 1.

Henry Adolph Magnus, M.D., has been appointed to the University Chair of Morbid Anatomy tenable at King's College Hospital Medical School, from April 1.

Sir Francis Fraser, M.D., F.R.C.P., Director of the British Postgraduate Medical Federation, has been reappointed Deputy Vice-Chancellor of the University for the year 1948-9.

Reginald Stephen Stacey, M.D., has been appointed to the University Readership in Therapeutics tenable at St. Thomas's Hospital Medical School, from June 1. From 1932-5 he was first assistant to the professor of medicine at St. Thomas's Hospital and from 1935-47 he was professor of pharmacology and therapeutics in the Royal Faculty of Medicine of Iraq, Bagdad, and physician to the Royal Hospital, Bagdad.

Herbert Edmund Vincent, M.D., has resigned the post of Chief Invigilator of the University, an appointment he has held for the past 40 years. Dr. Vincent qualified M.R.C.S., L.R.C.P. in 1887 and took the London M.B., B.S. in the same year, proceeding M.D. in 1888.

The following representatives of the University on the governing bodies of the institution indicated in parentheses are announced: V.E. Negus, M.S., F.R.C.S. (Institute of Laryngology and Otology), L.V. Cargill, F.R.C.S. (King's College School, Wimbledon), C.E. Newman, M.D., F.R.C.P. (West London Hospital Medical School), Ruth E. Proctor, M.B., Ch.B. (Battersea Polytechnic Training College of Domestic Science).

The following candidates have been approved at the examination indicated:

ACADEMIC POSTGRADUATE DIPLOMA IN MEDICAL RADIOLOGY—Part I: F.A. Adcock, H.S. Ali, J.M. Burbury, D. McC. Gregg.

### KING'S COLLEGE HOSPITAL MEDICAL SCHOOL

The King's College Hospital Medical School announces the foundation of the Wiltshire Memorial Research Scholarship and the Legg Memorial Lecture.

The Wiltshire Memorial Research scholarship was founded this year to commemorate Harold Waterlow Wiltshire, D.S.O., O.B.E., M.A., M.D., F.R.C.P., Physician to King's College Hospital from 1910 to 1925, and its primary object is to encourage research in cardiology. The holder must be a registered medical practitioner and will be called the Wiltshire Memorial Research Scholar. The appointment will be made by the council of the school on the recommendation of a selection committee of five to be appointed by the council. The appointment, which is part-time, is tenable for one year but may be renewed annually on the recommendation of the selection committee. The honorarium is at the rate of £250 a year, payable quarterly, and the scholar will be expected to carry out research under the direction of the physician in charge of the cardiology department. Leave of absence will be granted for six weeks each year.

The Legg Memorial Lecture also founded this year, is in memory of Thomas Percy Legg, C.M.G., M.S., F.R.C.S., Surgeon to King's College Hospital from 1910 to 1930, and will be given annually on a surgical subject on the invitation of the council of the medical school. The honorarium is the annual interest on £1,000 (at present about £25).

### UNIVERSITY OF MANCHESTER

The Council of the University has appointed Edward William Anderson, M.D., F.R.C.P., D.P.M., at present physician to the Maudsley Hospital, London, Professor of Psychiatry and Director of the Department from a date to be arranged.

### ROYAL COLLEGE OF SURGEONS IN IRELAND

The following candidates have received the Diploma of Fellowship: G.I. Fenton, E.A. McGivern, S.N. Rutherford, E.F. Shanahan.

## Medical Notes in Parliament

### NATIONAL HEALTH SERVICE

Mr. BEVAN stated on July 8 that by July 5 well over 30 millions of the total civilian population of 42 millions in England and Wales had been accepted by doctors under the National Health Service Act. He said there was a flood of forms still in the hands of doctors and executive councils which had not been counted.

#### Dental Service

On July 8 Mr. LIPSON asked the Minister of Health whether in view of the large number of dentists who had decided not to take part in the general dental service under the National Health Act, he would invite the Dental Consultative Committee to meet him again in order to try to find agreement on outstanding differences.

Mr. BEVAN said he would not do so. In his opinion the terms of service offered to dentists were generous and reasonable. He believed that most individual dentists would feel the same.

Mr. LIPSON then reminded Mr. Bevan of the happy result which had followed his gesture to the doctors. He asked whether the Minister would make a similar gesture to the dentists, so as to ensure that the benefits of the dental part of the Health Service reached the people at the earliest possible time.

Mr. BEVAN said he was convinced from the figures of the dentists joining up that very soon almost all dentists would be taking service under the Act. He added, "In any case we cannot submit to what may become, unless we are careful 'blackmail'."

#### Capitation Fee

Sir HENRY MORRIS-JONES asked how the amount of the capitation fee to medical practitioners under the National Health Act would be arrived at, what deductions came out of the 15s. 6d. per head, and how the amount for each area would be computed having regard to the proportion of the population who had not selected a doctor.

Mr. BEVAN said that detailed arrangements were still under discussion with the British Medical Association.

Sir HENRY reported that a large number of general medical practitioners were perturbed about this. They gravely feared their total emoluments would be considerably reduced below the pre-National Insurance income and they wished to know whether the total pool would be available to them.

Mr. BEVAN thought these doctors should await the result of discussions with representatives of the medical profession.

#### Hospital Boards and Committees

Sir IAN FRASER asked if regional and group hospital boards had power to co-opt extra members.

Mr. BEVAN replied that they had no such power, but regional hospital boards, hospital management committees, and boards of governors of teaching hospitals had power to appoint committees and subcommittees consisting partly of outside members and to delegate functions to them.

Mr. HEATHCOAT AMORY asked whether the Minister of Fuel and Power had authorized the granting of petrol allowances to members of the new hospital committees and boards on a scale sufficient to cover the requirements of this voluntary work.

Mr. ROBENS said adequate allowances would be made available, but, in common with all other supplementary allowances granted by the regional petroleum officers, the amount of the standard ration would be deducted if this had not already been done in respect of some other supplementary allowance issued for the same car.

#### Doctors and Patients under the Act

Mr. BOSWELL asked on July 2 whether Mr. Bevan before the National Health Service came into operation would ensure that lists of the doctors in the Service would be available in post offices and libraries so that patients could choose their doctor before July 5.

Mr. BEVAN said he had asked the executive councils to get these lists into the post offices on or as soon as possible after July 21. Some councils had already done so, but others including London, had not yet succeeded although they would do so as soon as possible. Any member of the public in an area where a list had not appeared could apply to the executive council for names of doctors on the list in his neighbourhood.

Mr. BOSWELL said that he himself had had trouble to find a doctor. He went to a post office but was told to go to the library and look up the *Medical Register*. He took the first three names on the local list, but found that the first address was a bombed site and that the other two doctors had gone away.

Mr BEVAN said he had always expected there would be inconvenience as a result of the tardiness of many doctors to sign on these lists. The official propaganda of the profession had told doctors there was no hurry to sign. The consequence had been a rush of doctors in the last few days which made it impossible for executive councils to complete the lists in time. Many local medical committees had asked those councils not to put up incomplete lists as to do so would be unfair to those doctors who had not yet signed. In many cases the delay was entirely due to the consequences of the propaganda of the medical profession. Mr Bevan said that he refused to accept responsibility for it. On doctor's lists up to June 26, 7,500,000 patients had already signed and 20,000,000 on the panel were automatically transferred.

Mr ASHETON was sorry Mr Bevan had put the blame on the doctors. The Opposition could not agree to that course. He asked where communications should be addressed in order to reach the executive councils.

Mr BEVAN said the names of doctors and addresses of the executive councils were placed in post offices and public libraries and so were available. Part of the difficulty lay in classifying doctors in areas such as London, where 1,000 general practitioners were involved.

Major BEAMISH said there was no more public-spirited body than the doctors and it was unfair to put the whole blame for the delay on them. The cause for the delay was Mr Bevan's obstinacy in the past.

Mr BEVAN said he put no blame on individual doctors, but the present difficulty must have been expected when the profession's propaganda clashed with the instructions given by the Ministry of Health. The position was perfectly clear to the public. It was essential for the doctor to be on the list before July 5 but the public could join at any time after.

Mr GALLACHER said the general opinion was that Mr Bevan had been, if anything, too generous and considerate to the doctors. He asked him to show equal consideration for the Scottish chemists.

### The Amending Bill

Sir HUGH LUCAS-TOOTH asked on July 1 when Mr Bevan expected to receive the report of the Committee which had been set up to advise him on certain clauses in the National Health Service Act and when Mr Bevan intended to introduce legislation giving effect to his undertaking so to amend the Act as to make it impossible to institute a full-time salaried medical service by regulation alone.

Mr BEVAN said he hoped to receive this report by the end of September. Amending legislation to cover anything necessary in the light of the report, together with the point mentioned by Sir Hugh, would be introduced as soon as possible thereafter.

Sir HUGH LUCAS-TOOTH asked whether Mr Bevan did not agree to the fact that the doctors were entering the Service before the settlement of the vexed question involved was an indication of their strong desire to give the Service a good start? He requested Mr Bevan to give a definite undertaking that he would implement the recommendations of the Committee when in due course they became known, and that he would not increase the salary element before legislation was introduced?

Mr BEVAN was glad to be able to say that despite the prophecies of certain pessimists the doctors were entering the Service in very large numbers, which was an indication of their confidence in the word of the Minister of Health. Before many years, or it might be months, Conservative members would claim credit for the Health Act, although they had voted against both the Second and Third Readings.

Mr WALTER ELLIOT retorted that the Health Service was due to the proposals of the Coalition Government. Conservative votes had been directed to the elimination of certain features.

Mr BEVAN said the fact was that the Opposition had been unable to secure the co-operation of the medical profession in any proposals.

### TUBERCULOSIS IN SCOTLAND

In the Scottish Standing Committee on July 1 the estimates for the Department of Health, Scotland, and for the National Health Service, Scotland, were considered.

Mr WALTER ELLIOT said he wished to discuss particularly the recent increase in tuberculosis in Scotland. Other important health questions would come up later. These would include the representations from doctors previously employed on the outdoor medical service of the Glasgow Corporation who considered they had received scurvy treatment in the new Health Scheme. These men after twelve years' service and at an average age of 50 found themselves rather stranded on the coming into force of the new Act. He noted that in discussing Scottish health the Committee had no figures later than December, 1946, in the Report before it. The maternal mortality rate had continued to fall in 1947, but the infantile mortality rate had risen

from 53.8 to 56. The tuberculosis rate had decisively changed for the worse. Deaths from tuberculosis in Scotland were the worst for twenty years, although figures for non-pulmonary tuberculosis continued to move in a satisfactory direction.

Deaths in Scotland from pulmonary tuberculosis in 1938 were 2,581. During the war the figures rose and fell again slightly, but in 1945 there were 2,932, in 1946 there were 3,231, and in 1947 there were 3,389. These figures contrasted with the general trend of tuberculosis throughout the world. The same trend was beginning to show in the industrial northern regions of England. In Scotland the death rate in 1946 was 64 per 100,000, a higher figure than any since before 1930. The so-called slump years, 1930-31-32 had figures of 63, 62, and 61. Notifications continued to rise. In 1945 notifications were 7,316, in 1947 there were 7,943. This compared with notifications in 1938 of 4,793. The Chief Medical Officer for Scotland had said there was probably no simple explanation of the increase, but Mr Elliot contended that the rise demanded some further inquiry. He did not believe that 2,700 calories per person was adequate, and it might be that a scale of diet adequate for clerical occupations was not adequate for the heavy industries.

He mentioned the shortage of accommodation in sanatoria. This was not really a shortage of beds, but a shortage of staff. There was nearly a 50% deficiency of nurses in sanatoria and the isolation of infected cases was not taking place. It was rash for the Secretary for Scotland to push through everyone's letterbox a leaflet saying, 'If you need it, you can have treatment in hospital either as an in-patient or as an out-patient.' That pledge could not be implemented. For comparison, Mr Elliot mentioned that the deaths from tuberculosis were falling in England as a whole but were going up in Durham, Lancashire, and the West Riding, though not in the more agricultural counties of Cumberland and Northumberland. The increase was less well shown in Liverpool and Manchester and was not shown at all in Sheffield and Leeds. These figures required investigation and all the more so because an inquiry by the Medical Research Council at the instance of the Ministry of Health into tuberculosis in Germany reported that the rates for Hamburg were considerably less than those obtaining in Glasgow.

### Government Reply

Mr FRASER replying for the Government, said the Scottish Health Report for 1947 had been in the hands of the printers for some time. Colonel Elliot had compared the present figures for deaths from pulmonary tuberculosis with those in the slump years, but this was a disease the germs of which might remain quiescent for ten years or more and then become active. It might be that the undernourishment of people in Scotland in the early thirties had something to do with the rise in tuberculosis notifications and deaths in the war years. Among young women in Scotland between 20 and 25 years of age who died from tuberculosis in recent years were persons who contracted the disease ten, fifteen, or more years ago. The same was true of men up to 45. The standard of nutrition in Scotland among industrial workers was comparable with that of such workers in England, and therefore the Committee had to look beyond nutritional standards for the cause of the continuing high incidence of tuberculosis in Scotland. It was true that the incidence in Hamburg was on a downward curve, but in Berlin and other parts of Germany a different story would be told. It was regrettable that they had got back to the 1920 level of notifications. Deaths, too, had increased, but not so markedly. The continuing increase in contrast with the increase during the war period was very nearly peculiar to Scotland. Mass radiography had discovered more than 1,000 cases in Scotland, but the death figures were the really important ones. Hospital accommodation for treatment was there if the nursing staffs were available. They had at present 2,324 sufferers on the waiting list in Scotland, compared with 771 in 1942. The number of beds occupied by tuberculous patients at the end of 1947 was 5,493, an increase of 277 during the year. In general hospitals and other hospitals more beds could be made available for these patients if there was the nursing staff. In December, 1946, 1,245 nurses were in sanatoria and the tuberculosis wards of infectious diseases hospitals. There was only a very small number of part-time nurses. By March 31, 1948, the whole-time staff had gone up to 1,318 and the part-time staff to 599. The estimated additional requirement for sanatoria and infectious diseases hospitals was 1,300. The overall shortage of nurses in Scotland was estimated to be about 5,000, although nearly 3,500 more whole-time nurses were employed in Scotland than before the war. Superintendents of sanatoria and general hospitals in Scotland agreed that the way to get nurses for tuberculosis work was not to isolate them and not to give hospitals over completely to the treatment of tuberculosis, so that there could be a frequent interchange of nurses between general wards and tuberculosis wards.

Col HUTCHISON said the incidence of tuberculosis among nurses allotted exclusively to that work was lower than among nurses undertaking general hospital work, and that both had a lower incidence of tuberculosis than the same groups in outside life.

Mr FRASER said he could not confirm this at the moment. The most important long-term remedy for tuberculosis was improved social conditions for the mass of the working people of Scotland.

Mr JOHN HENDERSON said he was told by eminent medical men in Glasgow that of all branches of medical science the treatment of tuberculosis had made least progress during the last twenty-five years. Yet the Government had been responsible for almost the entire payment for this treatment which was more or less carried out by the local authority on a policy laid down by the Government. That did not indicate a happy future for the nationalized medical service. He suggested that infection had been increased during the past winters by the keeping of the windows of houses closed because of the difficulty of getting sufficient heating.

### BCG and Streptomycin

Col HUTCHISON doubted whether there was a valid argument in saying that cases which became apparent now could be traced back over ten years. There was a remarkably low rate of tuberculosis in Scandinavia where BCG immunization was being used. This did not prevent the disease but made resistance to it much stronger.

Mr SCOLLAN testified that as a young man he had been cured of tuberculosis by a South African native root called 'umkaloabo' brewed like tea and administered to the patient.

Sir BASIL NEVEN-SPENCE said that in Shetland the mortality rate was 104 per 100,000 as against an average county mortality rate in Scotland of 55. Yet bovine tuberculosis had been completely eradicated in Shetland. He was perfectly sure that in the Highlands and Islands the key to the problem was housing.

Mr NIALL MACPHERSON spoke of mass radiography and said that at Edinburgh University the students had an annual check-up. Was it intended to do the same in schools and when men went to register for national service? It seemed to him necessary that miners should be examined periodically. The Scottish Estimates spoke of the purchase of streptomycin for research but his information was that that drug was severely restricted in this country because owing to the shortage of dollars, the Government was not prepared to purchase it. He believed that only one thoracic unit had been established in Scotland, at Mearns-kirk. Were others being established?

Mr WOODBURN said tuberculosis spread more easily under conditions of overcrowding but it did not necessarily follow that overcrowding brought tuberculosis. The cause was probably not so much that people were overcrowded but that they developed certain habits of living too close together without fresh air. People stayed in the tenements and never came into the fresh air. Most of the tuberculosis in Western Scotland came from contacts with infected people. A good deal had still to be done in making improvements in order to get a greater recruitment of nurses. It seemed that Highland people were less immune if they came to Glasgow than the people who were born and bred there. Yet in the Highlands and in the Outer Isles people lived closely in their houses and shut out the fresh air. The Department of Health for Scotland was opening hospitals and trying to get better sanatoria. It was investigating BCG immunization and streptomycin but had to be careful about raising hopes until cures were certain. The Department might save many lives by sending the children of patients into residential educational centres and getting nurses to nurse the children even if they would not nurse the patient. The question of overcrowding and other matters could be discussed when the Committee came to the Health Estimates.

### FACTORIES BILL

The debate on the second reading of the Factories Bill was resumed on July 2. Mr PIRATTIN, discussing the supervision of canteens in factories, pointed out that local sanitary inspectors had some responsibility for the supervision of kitchens, and asked the Minister to say in which way the two sets of inspectors would work together. The provision of washing facilities was one of the most abused sections of the existing Factories Act. It was not a matter of introducing new Clauses but primarily one of implementing them.

Mr ASHETON said it was now clear that the transfer of the duties of the factory inspectorate from the Home Office to the Ministry of Labour had proved to be successful. The department of factory inspection was a fine one and the men in it performed their duties to the satisfaction of both sides in industry.

Dr MORGAN said the Government had brought in a National Health Service Act, and the complement to that should have been the introduction of an Industrial Medical Service Act. The trade union movement disapproved of the provisions in Clause 7 concerning examining surgeons. A doctor selected by employers or the industrial medical officer appointed by the employer in a factory would under the Bill have the option of being appointed as a factory doctor and would be able to undertake all the duties formerly imposed on the examining surgeon. This Bill enabled that doctor appointed by the employer to have the decision not only about the diagnosis in an individual case but on the fitness of a recruit for work. Representations had been made to the Minister by the Trade Union Congress to prevent this from happening. Dr Morgan suggested that the Minister should take Parliamentary authority to say that the company's doctor should not usually be appointed as factory doctor but that the Minister on the advice of his inspectors and medical officers should have the right in particular cases to make this appointment. Dr Morgan complained that there was no general industrial medical service and too few medical factory inspectors. There was no scheme for the appointment of medical officers for the smaller factories in which there were industrial risks. When the employer's doctor, who was also made the factory doctor was to conduct examinations, who could guarantee the confidential relationship between the recruit to industry and the doctor? Who would guarantee that the records of the doctor would be kept secret? They would presumably be kept somewhere in the factory. In spite of these dangers the medical profession had not raised an objection to the risk of this confidential information being disclosed. If the Minister could do nothing else he could insist that permission must be obtained in cases where the employer's doctor would act for the employer against the man.

Major HAUGHTON said urgent representations had been made to him that there was a great shortage of protective clothing and that in consequence serious trouble arose in certain industries.

Mr WEITZMAN was glad to see that in the provision of seating facilities the frailty of males was recognized. He could have wished that the opportunity had been taken in the Bill to prohibit or limit the conversion of dwelling-houses or parts of them into workrooms for small factories. It was necessary that the definition of "factory" should be extended. Injuries had occurred in technical colleges and in institutions which did not come within the definition of a factory.

Mr SPARKS said a case could be made out for the establishment of an industrial medical service and the Bill did not go far enough in that direction. He thought that enough was not done to ensure that young people were advised to enter the kind of industry suited to their health and physique. A case could be made for bringing the railways within the scope of the Factories Acts.

Mr ISAACS replied to the debate. He had a great deal of sympathy with Dr Morgan's point about factory doctors, although he believed that a doctor who was the firm's doctor would not be swayed from his professional ideals. In moving the second reading he had given an undertaking to examine carefully any amendments which might be brought forward on the issue of certificates that diseases arose out of a man's employment. The Government did not wish to spoil the value of the factory doctor by having doubts cast upon his independence. He assured Dr Morgan that he would not have introduced the Bill if it were likely to retard the coming into operation of a full industrial medical service.

The Bill was then read a second time.

### Medical Examination of Prisoners

During the Report Stage of the Criminal Justice Bill in the House of Lords on June 29, on Clause 29, which concerns Remand for inquiry into physical or mental condition, Lord BALFOUR OF BURLEIGH moved to leave out "physical or". He pointed out that in the 1939 draft of the Bill the Clause dealt only with mental cases. An assurance had then been given in the House of Commons by the Solicitor-General that no physical examination of common prostitutes was contemplated. He was alarmed because the inclusion of physical examination in the Bill was simultaneous with the new National Health plan, which involved changes in the whole service for treating venereal diseases. Some safeguard was needed against abuse. The Ministry of Health had issued a circular to local authorities stressing the importance of treating information about persons under treatment for V.D. as confidential "even though the revocation of the 1916 Regulations repeals the statutory requirement to this effect." Lord Balfour could not understand why the statutory requirement should have been repealed. What was to be the position of a medical officer of health when the

magistrate asked for the information? He would no longer have the statutory protection of secrecy. It might be that the divisional surgeon would have to give the information.

Lord CHORLEY said there was at present power to remand a person in order that an examination whether physical or mental, might be made. In the past there had been prisoners who could not afford a medical examination at their own expense, and as a result the courts refused bail. The Clause gave opportunity to remand the man and for the court to see that the medical examination took place. In the case of prostitutes there was no alteration in the law, and the practice followed in the past would be followed in the future. That practice was never to submit them to a vaginal examination without their consent. Replying to Lord LLEWELLIN, Lord Chorley went on to say that the Government was unwilling to accept an amendment providing that no physical examination of a remanded prisoner should be made without consent. Under prison rules provision was made for examination. The provision for examination of women charged with soliciting was exactly the same as for any other person charged before the court. That prisons never subjected a woman to a vaginal examination without her consent was a well-understood principle, though not written into the prison rules. To that principle the Government intended to adhere.

The LORD CHANCELLOR said that if someone had only one lung it was relevant for the court to know that before deciding what punishment to give. The more intimate examination which had been mentioned had never been made and would not be made save with the consent of the prisoner.

Lord CALVERLEY said that in any large prison persons on remand could be found either in the verminous section or in the V.D. section.

Lord GODDARD said a physical examination was made of all young offenders who might be sent to Borstal.

Lord Balfour of Burleigh's amendment was negatived.

## EPIDEMIOLOGICAL NOTES

### Discussion of Table

In *England and Wales* increases in the number of notifications of scarlet fever 107 and acute poliomyelitis 12 were recorded and decreases in whooping-cough 283 acute pneumonia 83, measles 53, dysentery 27, and diphtheria 21.

The rise in the incidence of scarlet fever was mainly confined to the midland counties, the largest increase was Lancashire 27. The decrease in the notifications of whooping cough was general throughout the country, the largest falls were Kent 77 and London 56. No large fluctuations were recorded in the local returns of acute pneumonia and in most areas there was a small decline.

The trends of measles varied considerably. The largest decreases in notifications were Kent 106, Sussex 88, Derbyshire 84 and Middlesex 52, the largest increases were London 125, Monmouthshire 61, Yorkshire East Riding 59, and Hertfordshire 49. The largest local fluctuation in the trends of diphtheria was a decrease of 15 in Lancashire.

The returns of dysentery were the lowest for six months. The chief centres of infection were Lancashire 14, Yorkshire West Riding 13 and London 10. Notifications of acute poliomyelitis were the largest for eighteen weeks. The counties with more than one case of poliomyelitis were London 7 (Westminster 2, Woolwich 2), Yorkshire West Riding 5 (Darton U.D. 3), Middlesex 4 (Heston and Isleworth M.B. 3), Essex 2 and Cheshire 2.

In *Scotland* a decrease was recorded in the incidence of most infectious diseases and the only exception was an increase of 20 in the notifications of scarlet fever. In the county of Lanark a decrease of 34 in the notifications of scarlet fever was reported. In Edinburgh the notifications of dysentery increased from 1 to 10. An outbreak of gastro-enteritis occurred in Paisley during the week and 7 infants have died.

In *Eire* an increase of 23 was reported in the notifications of diarrhoea and enteritis, while decreases were recorded for scarlet fever 22 and whooping-cough 19. Of the 46 cases of diarrhoea and enteritis 37 were notified in Dublin C.B. An outbreak of infective hepatitis involving 29 persons was notified from Tipperary, Shevardagh R.D.

In *Northern Ireland* the notifications of scarlet fever in the two county boroughs increased by 6 but a decrease of 11 was reported in the remainder of the country.

### Week Ending July 3

The notifications of infectious diseases in *England and Wales* during the week included scarlet fever 1 532, whooping-cough 2 907, diphtheria 141, measles 8 987, acute pneumonia 359, cerebrospinal fever 42, acute poliomyelitis 36, dysentery 69, paratyphoid 6, and typhoid 6.

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended June 26.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland. Figures of Births and Deaths and of Deaths recorded under each infectious disease for (a) The 126 great towns in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns in Northern Ireland. A dash — denotes no cases, a blank space denotes disease not notifiable or no return available.

Disease	1948					1947 (Corresponding Week)				
	(a)	(b)	(c)	(d)	(e)	(a)	(b)	(c)	(d)	(e)
Cerebrospinal fever Deaths	34	1	17	4	1	57	8	24	1	—
Diphtheria Deaths	137	17	44	6	1	182	15	47	31	5
Dysentery Deaths	64	10	39	1	—	66	7	14	—	—
Encephalitis lethargica acute Deaths	—	—	—	—	—	2	1	—	—	—

Poliomyelitis acute Deaths§	27	7	2	1	—	56	5	5	5	2
Puerperal fever Deaths	—	2	12	—	—	—	3	13	—	—
Puerperal pyrexia   Deaths	109	13	5	—	—	94	10	12	—	2
Relapsing fever Deaths	—	—	—	—	—	—	—	—	—	—
Scarlet fever Deaths†	1 649	103	394	40	36	947	69	110	25	38
Smallpox Deaths	—	—	—	—	—	2	—	—	—	—
Typhoid fever Deaths	3	—	3	1	—	10	—	1	5	7
Typhus fever Deaths	—	—	—	—	—	—	—	—	—	—
Whooping-cough* Deaths	2 803	217	38	86	12	2 052	188	78	73	5
Deaths (0-1 year) Infant mortality rate (per 1 000 live births)	256	40	46	17	8	365	56	65	22	16
Deaths (excluding still births) Annual death rate (per 1 000 persons living)	4 018	615	586	151	137	3 982	657	562	140	122
Live births Annual rate per 1 000 persons living	7 743	1246	1015	448	246	9 012	1404	1096	459	265
Stillbirths Rate per 1 000 total births (including stillborn)	241	35	26	—	—	272	27	30	—	—

\* Measles and whooping cough are not notifiable in Scotland and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county) will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county) and Northern Ireland.

§ The number of deaths from poliomyelitis and polio encephalitis for England and Wales, London (administrative county) are combined.

|| Includes puerperal fever for England and Wales and Eire.

## Medical News

### Peckham Health Centre

Queen Mary, the Prime Minister, Sir Stafford Cripps, and other distinguished persons were present at the showing of a film produced by Mr Paul Rotha on the Peckham Health Centre and afterwards at the centre itself. The centre is an interesting experiment in the healthy use of community leisure, the family being the unit of membership of a club providing facilities for swimming, gymnastics, badminton, dancing, billiards, and so forth, and medical supervision and advice. The film has a certain pathos in showing the isolation of a family in the wilderness of houses that make up a "conurbation," but it fails to convey any idea of the experiment the directors of the centre are trying to carry out. The centre itself is so much better than the film that those who see only the latter are unlikely to be roused to enthusiasm. Whether any observations of real scientific value will emerge from the Peckham experiment remains to be seen. But there can be little doubt that similar centres—properly called "health"—in our large cities would do much to promote health and happiness among those who, through sheer density of population, must find it difficult to maintain the sense of belonging to a community.

### Empire Medical Advisory Bureau

The Empire Medical Advisory Bureau set up by the British Medical Association was formally opened on the afternoon of Tuesday, July 13, by Lord Addison. Among the many distinguished guests present at the opening ceremony and at the sherry party which followed were representatives of the High Commissioners for Australia, Canada, New Zealand, India, Pakistan, Ceylon and Southern Rhodesia. The Empire Medical Advisory Bureau is directed by Dr H A Sandiford and is intended to assist in every way practitioners from the Dominions and Colonies who want to take advantage of the facilities available in this country for post-graduate study.

### Entered NHS

The Ministry of Health announces that 19,096 doctors in England and Wales had joined the National Health Service by July 5, and 2,245 in Scotland by July 3.

### World Health Organization

On July 12 the Executive Board of the World Health Organization was elected by the World Health Assembly. Under the constitution one third of the members retire each year and it was therefore decided by drawing lots which States should serve for one year and which for two. Australia, Ceylon, the United Kingdom, United States, Norway, and Persia will serve for one year. Brazil, China, Mexico, France, Russia, and Egypt for two years. And White Russia, India, Poland, South Africa, the Netherlands and Yugoslavia for three years. It had previously been unanimously decided that the headquarters of the World Health Organization should be in Geneva. This decision is subject to final confirmation by the General Assembly of the United Nations but is not likely to be opposed.

### Whole-time Salaried Specialists

A special general meeting of the Association of Municipal Specialists was held on June 28 to discuss the future of the association under the National Health Service. It was unanimously agreed that the association should continue to serve whole-time medical specialists and in future the association will be known as the Association of Whole-time Salaried Specialists. All whole-time specialists will be eligible for membership. Further information can be obtained from the office at 45 Lincoln's Inn Fields, WC2 (Telephone HOLborn 3474).

### Medical Photographers

A meeting of medical photographers was held at the Institute of British Photographers on June 11. Mr L J Hibbert, Principal of the School of Photography, Polytechnic Regent Street and chairman of a committee of medical photographers presented a report which the committee had prepared on the necessity for medical photography, its scope, the training and qualifications required, and the salaries that should be paid to qualified persons. The report will be submitted to the Ministry of Health. The meeting then agreed to start a register of medical photographers. It will be limited to members of the institute and those who have been in practice as medical photographers for not less than two years. The meeting concluded by deciding to form a medical group of the Institute of British Photographers and its organizing committee was appointed.

### Sir Alexander Fleming

At Canada House, London, on July 6 the High Commissioner for Canada presented Sir Alexander Fleming with the Gold Medal of the Canadian Pharmaceutical Society in recognition of his work for humanity in the discovery of penicillin.

### Royal Medical Psychological Association

The annual dinner of the Royal Medical Psychological Association was held at the Café Royal on July 7 with the President Dr W Rees Thomas in the chair. There was a good attendance of members and their guests and delegates from the USA, Australia, France, Belgium, and India were present. The toast of the association was proposed by Mr John P Edwards, MP, Parliamentary Secretary to the Ministry of Health who referred to the help given by the association to the Ministry when the mental health side of the National Health Service was being planned. Mr Edwards stressed the determination of the Ministry to remove mental hospitals for all time from their previous position of isolation. Dr Rees Thomas, in his reply, said that psychological medicine was at a disadvantage compared with other branches of medicine because it was tied up with the law. Workers in this field were to some extent in the hands of the legislators whose task it is to give conditions which would lead to sound mental health. On the clinical side he believed that progress would be hastened by a wide development of the outpatient clinic system. The toast of the guests, among whom were the Presidents of the Royal College of Physicians and the Royal College of Obstetricians and Gynaecologists, was proposed by Dr R Strom Olsen. Miss D M Smith, Chairman of the General Nursing Council, in her reply, congratulated the association on its decision to hand to the statutory body the responsibility for conducting the examination of nurses who worked in mental hospitals. The toast of Medicine was proposed by the Bishop of Lincoln, and replied to by Dr A Pool. Both speakers, while by no means in favour of all forms of so-called faith healing, referred to the very real value of spiritual healing and welcomed the agreement which had been reached between the Council of the BMA and the Churches Council of Healing (see *Supplement*, Nov 8, 1947, p 112).

### Cameron Prizewinner

After receiving the Cameron Prize in Edinburgh for his outstanding work on the effects of drugs on the thyroid gland, Professor E B Astwood, endocrinologist at the Pratt Diagnostic Hospital in Boston, U.S.A., is in London until July 23 lecturing for the British Medical Association and visiting endocrinological departments under the auspices of the British Council.

### Sickness Benefit

If a medical officer of health considers it advisable to exclude a person from work because he or she is under observation as a contact or carrier of infectious disease, he now has power, under Ministry of Health Circular No 115/48, to issue a certificate which will enable the person concerned to claim sickness benefit from the Ministry of National Insurance.

### Oc ogeraran

With its current number the *Practitioner* celebrates its 80th birthday since it was started in 1868 under the editorship of Dr F E Anstie, of the Westminster Hospital, and Dr H Lawson, of St Mary's. Sir Heneage Ogilvie reviews the changes that medicine has undergone since that time from clinical impressions to statistical inquiry, from polypharmacy to a more precise therapy, from individualism to organization. Professor Ryle writes on one of medicine's newest branches—social medicine—and Dr Leslie Banks of the Ministry of Health expounds the National Health Service Act.

### Mr R W Raven

Mr R W Raven, OBE, FRCS, has been elected a corresponding foreign member of the Roman Surgical Society.

### Superintendents of Mental Hospitals and Institutions

Because the Lunacy Act, 1890 was repealed on July 5 and the Mental Deficiency Regulations 1935 are being rewritten the Minister of Health has made a regulation requiring the appointment of superintendents of mental hospitals or institutions for mental defectives administered by Regional Hospital Boards. The superintendent will normally be a medical practitioner, if a Board considers that an institution might have a lay superintendent it should inform the Minister of its views. The superintendent will be responsible for the general management of the hospital or institution subject to the direction of the Regional Hospital Board or hospital management committee, and he has power to suspend any officer.

**Chevalier of the Legion of Honour**

The President of the French Republic has conferred the decoration of Chevalier of the Legion of Honour upon Mr. C. Bowdler Henry, MRCS, LRCP, LDS, in recognition of services rendered during the war.

**Brahan Convalescent Home of Perth Royal Infirmary**

Speaking at the opening ceremony of the Brahan Convalescent Home of Perth Royal Infirmary on June 12, Sir Andrew Davidson, Chief Medical Officer, Department of Health for Scotland, said that we were on the eve of great new developments in the health services. The opening of that beautiful new convalescent home seemed to deny the contention that local interest and initiative were likely to disappear from the great national hospitals. Another misconception which it destroyed was that there was no place in the health services nowadays for voluntary effort. Never, in fact, had there been more need for service—in the true sense of the word—as in these days when the horizon of health effort was widening so rapidly. The administration of the National Health Service was built on voluntary service. In Scotland five Regional Hospital Boards and 25 local executive councils, all comprising voluntary members expert in various branches of the work, were already wrestling with problems of organization and administration of the National Health Service, the Central Health Services Council set up to advise the Secretary of State on all matters concerning the Service—also comprising experts giving voluntary service—had been constituted and had set to work, and the preventive services of local authorities were administered by health committees consisting of members giving freely of their time and energy.

**Award of Scholarships**

The following scholarships have been awarded at the Royal Free Hospital School of Medicine for the year 1948-9: *A. M. Bird Entrance Scholarship* Miss S. J. R. Stockton, Queenswood School, Hatfield; *Mabel Sharman Crawford Scholarship* Miss J. E. Arnott, Shrewsbury High School; *Lieut. Edmund Lewis (RAF) and Lieut. Alan Lewis (RNAS) Memorial Scholarship* Miss M. C. Lewin, Royal Free Hospital School of Medicine; *A. M. Bird Scholarship for Clinical Studies* Miss B. I. Bing, Royal Free Hospital School of Medicine; *Sir Owen Roberts Memorial Scholarship* Miss M. W. Sturges, Royal Free Hospital School of Medicine.

**Wills**

Sir Henry Lindo Ferguson, of Dunedin, New Zealand, left estate in England valued at £8,490 12s 8d. He left £1,000 to the New Zealand Medical Benevolent Fund to provide annuities for aged and incapacitated medical men and their widows. Dr. James Herbert Wright, formerly M.O.H. for Sutton Coldfield, left £13,431. Dr. Edward Deanesley left £42,265. Dr. John Duncan McVean left £22,909, and Dr. Egerton Allen Ferguson, of Salford, left £8,806.

**COMING EVENTS****British Standards Institution**

The annual general meeting of the British Standards Institution will be held on Wednesday, July 21, at 3 p.m., at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, WC2.

**Royal Institute of Public Health and Hygiene**

The president and council of the Royal Institute of Public Health and Hygiene will give a reception to the Empire delegates to the International Congress on Physical Education, Recreation and Rehabilitation at the institute (28, Portland Place, London, W.) on Thursday, July 22, at 6 p.m., when the guests will be received by the president, the Rt. Hon. Walter Elliot, M.C., F.R.C.P., F.R.S., M.P.

**Biochemical Society**

The 268th Meeting of the Biochemical Society will be held at the Biochemical Department, the University, Glasgow, on Friday and Saturday, July 23 and 24, starting each day at 11.15 a.m.

**Edinburgh Lectures**

In connexion with the postgraduate course in medical sciences which began on July 5 a series of open lectures has been arranged by the Edinburgh Postgraduate Board for Medicine to be given in the anatomy lecture theatre of the University of Edinburgh. On July 12 Professor A. C. Frazer spoke on "Fat Digestion and Absorption" and on July 15 Sir Jack Drummond, F.R.S., discussed "The Practical Significance of Wartime Experience in the Field of Nutrition." The remaining lectures will be announced in the diary column of the *Journal* week by week. All graduates and students are invited to attend the lectures.

**SOCIETIES AND LECTURES****Wednesday**

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE—At Anatomy Lecture Theatre, Edinburgh University, July 21, 3.30 p.m. "Blood Flow Through Extremities" by Prof. H. Barcroft.

**Thursday**

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, London, W.C.—July 22, 5 p.m. "The Changes in Volume and Distribution of Body Water under Conditions of Stress" Bernhard Baron Lecture by Prof. John Beattie.

**Friday**

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE—At Anatomy Lecture Theatre, Edinburgh University, July 23, 4.30 p.m. "The Neutral 17-Ketosteroids" by Professor G. F. Marrian.

**Saturday**

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES, 11 Chandos Street, London, W., July 24, 2.30 p.m. Annual general meeting. Election of officers, etc. "The Pathology of Gonorrhoea," Address by the President, Dr. A. H. Harkness.

**BIRTHS, MARRIAGES, AND DEATHS****BIRTHS**

Crawford—On July 1 1948 at Edgbaston Maternity Nursing Home Birmingham to Mary (née Seton) wife of W. Cowan Crawford LRCP & SEd L R F P S Glas a daughter.  
Crockett—On July 9 1948 at Lansdowne House Lansdowne Road London W to Joan and Dr. Gerard Crockett a son.  
Devlin—On June 27 1948 to Dr. Audrey (née Conyngham) and Dr. H. R. T. Devlin 18a Woodlane Falmouth Cornwall a daughter—Melian.  
Dobson—On July 6 1948 at Tany Bryn Imperial Road Matlock to Mary Belle wife of Dr. R. B. Dobson of Matlock a daughter.  
Griffiths—On June 12 1948 at Kidderminster to Fifi (née Gurdon QARNNS) wife of Dr. P. D. Griffiths a daughter.  
Jeanes—On July 1 1948 at Woolwich War Memorial Hospital to Joyce (née Johnson) wife of Dr. C. W. L. Jeanes a son—David Lloyd.  
McDonald—On July 3 1948 at 9 Grosvenor Street Edinburgh to Margaret wife of Surgeon Lieutenant R. S. McDonald a daughter.  
Marsh—On July 1 1948 to Bobbie (née Robinson) wife of Dr. Alan Marsh 3 Clannricarde Gardens Tunbridge Wells a brother for Susan—Michael Rupert.  
Mitchell—On July 7 1948 at Dudley Road Hospital Birmingham to Elsie wife of Gardiner Mitchell FRCS Ed twin sons.  
Tabbush—On July 1 1948 at St. Chad's Hospital Hagley Road Birmingham to Anne Jacqueline wife of Dr. Henry Tabbush a son—Paul Martin.  
Watson Jones—To Ann and Dr. K. Watson Jones of Sheldon Birmingham a daughter.

**MARRIAGE**

Marsden—Coope—On July 3 1948 at St. Augustine's Church Penarth Henry Basil Marsden M.B. Ch.B. to Pamela Jill Coope M.A. B.Chir. by the Rev. G. H. A. Stephens M.A.

**DEATHS**

Alexander—On June 30 1948 David Alfred Alexander M.B. Ch.B. of 112 Pembroke Road Clifton Bristol.  
Bidwell—On July 4 1948 at Bloemfontein South Africa Charles Hugh Bidwell MRCS LRCP aged 76.  
Cookson—On July 7 1948 at Heatherdown Blyden Somerset Reginald George Francis Cookson LRCP & SEd L R F P S Glas of Clifton Bristol.  
Crawford—On July 8 1948 Herbert de Lisle Crawford M.D. M.Ch. FRCSI of 60 Russell Square London W.C. son of the late Rev. William Crawford Dublin.  
Davis—On July 5 1948 at 70 Brighton Road Worthing Everard Inscal Davis MRCS LRCP aged 74.  
Douglas-Webster—On July 2 1948 in South Africa Edgar Maurice Douglas Webster LRCP & SEd L R F P S Glas.  
Forbes—On July 8 1948 at Rochester John Turnbull Thomson Forbes MRCS LRCP Wing Commander RAFMS retired.  
Green—On July 5 1948 at 266 Stockport Road Manchester Edwin Alan Thomas Green M.C. MRCS LRCP LDS.  
Greene—On June 26 1948 at Killybegh Co. Down Thomas Adrian Greene LRCP & SEd L R F P S Glas.  
Jacobs—On July 5 1948 Lawrence Jacobs M.B. Ch.B. of 43 Circus Road St. John's Wood N.W.  
Kitchen—On July 4 1948 Harold Ernest Kitchen B.A. MRCS LRCP of 4 Auckland Terrace Ramsey Isle of Man aged 71.  
MacArthur—On July 5 1948 at Glasgow Royal Infirmary Duncan S. M. MacArthur M.B. Ch.B.  
McClennan—On June 30 1948 at 14 Shanshieve Drive Newcastle Co. Down James Martin McClennan M.B. Ch.B. BAO DPH.  
Pepper—On July 9 1948 Charles Edward Pepper M.B. Ch.B. Ed. of 4 Park Hill Road Croydon aged 71.  
Simon—On July 1 1948 David James Simon LRCP & SEd L R F P S Glas of 12 Bewick Road Gateshead aged 56.  
Smith—On July 10 1948 Hugh Bernard Willoughby Smith FRCS of Gainsborough Lincs aged 68.  
Symons—At Church Crookham Hants Sir Thomas Henry Symons K.B.E. CSI KHS MRCS LRCP Major General IMS retired. Lte Director-General IMS aged 76.  
Wright—On June 27 1948 Stanley Nimran Wright M.Sc. M.B. Ch.B. DPH of Ravell's Upland Road Spital Park Bromborough aged 58.

## Any Questions ?

*Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.*

### Adenosine in Angina of Effort

**Q**—Adenosine and adenosine phosphate are reported to relax smooth muscle dilate the coronary arteries and cause a fall in blood pressure. In addition they slow the heart presumably thereby reducing its oxygen requirements. Have these drugs ever been used in angina of effort? Possibly the increased coronary diameter would be offset by the decreased aortic pressure. Could adenosine then be used with ephedrine or adrenaline?

**A**—There does not appear to be any reference to adenosine or adenosine phosphate as a therapeutic agent for angina of effort. In 1929 Drury and Szent-Gyorgyi isolated adenylic acid, a closely related compound, from cardiac muscle. Adenosine phosphate is present in all muscle and plays an important part in its metabolism. Many drugs with an effect on the heart—for example, pilodyn and lecardol—contain a certain amount of adenosine and their action probably depends on this.

Much experimental work on heart preparations, uterine muscle, and living animals has been done, especially by A. M. Wedd (*J. Pharmacol.* 1933, 47, 365). Given intravenously adenosine decreases the rate of the heart and causes dilatation of the coronary and peripheral vessels; there is also a paralytic action on unstriated muscle tissue which lasts only a short time. In man adenosine given intravenously results in a heaviness in the chest, breathing is increased in depth and frequency, and there is a sensation of heat in the head and body generally. A momentary rise in pulse rate is followed by a bradycardia, depending in degree on the dose of drug used. The PR interval is prolonged, Wenckebach phenomena occur, and heart-block ensues. The T wave is lowered. These changes are induced more easily if cardiac defects already exist. Kalra (*Acta med. scand.* 1938, Suppl., 89, 239) reports the treatment of a case of paroxysmal tachycardia; his results were not convincing. He refers to two similar cases successfully treated by Jagrehs in 1933. Experimentally produced auricular fibrillation has been successfully treated with adenosine.

Structurally related drugs are theophylline and theobromine, these have the advantage of being effective by mouth. The action of adenosine on the coronary vessels takes place in the presence of meclocholyl, pitressin and barium, which normally diminish the coronary blood flow. There is no reason why it should not be tried intravenously in the correct dosage for angina of effort. One would hesitate to use adrenaline or ephedrine in an attack of angina of effort because of the danger of inducing ventricular fibrillation.

### Idiopathic Cheiropompholyx

**Q**—Is idiopathic cheiropompholyx always due to an external irritant? If not can it be due to the ingestion of some antigen to which the patient is sensitive—for example an antigen in eggs or egg powder? Are any vitamins of use in preventing attacks? Would stilboestrol help a woman of 67 in preventing attacks? What can be done to cure this distressing complaint?

**A**—Idiopathic cheiropompholyx is a constitutional affection of emotional and nervous origin. It is associated with hyperidrosis and often with an anxiety state, though hot weather predisposes to the eruption. The condition can be evoked upon occasion by contact with external irritants, more particularly with substances to which the patient is sensitized. It can upon occasion arise as an 'idic' reaction usually secondary to ring-worm infection of the feet. It can also be simulated by a small pattern of toxic erythema limited to hands or hands and feet and due to the ingestion of foods or drugs or to toxins, to which the patient has become sensitized. Eggs are not a very likely cause of the eruption and vitamins have no particular

prophylactic value, though on general grounds vitamin B therapy is of value in neurodermatitis.

In a woman of 67 a careful general overhaul would be necessary, and it is unlikely that stilboestrol would be indicated in treatment. In the absence of any organic factor the emotional state should be given attention, and symptomatic relief might result from the taking of phenobarbitone in small doses from fractional doses of superficial x-ray therapy, and from blind local applications such as calamine liniment.

### Sulphonamides and Agranulocytosis

**Q**—(a) Is the simultaneous administration of barbiturates and sulphonamides more likely to induce agranulocytosis than the use of the latter alone? (b) Is the administration of pyridoxin with sulphonamides used in preventing agranulocytosis?

**A**—(a) There is no evidence that this is so. On the other hand, a sedative which should never be given during sulphonamide treatment is amiodopyrine. (b) Pyridoxin has been used successfully in preventing granulocytopenia during treatment with thiouracil. If there is no information about such an effect during sulphonamide treatment (and apparently there is not) it is because sulphonamides so rarely affect the bone marrow that proof of efficacy in this connexion would be hard to obtain.

### Hypersensitiveness to Wasp Stings

**Q**—I have a friend who lives in dread of wasps. He was first stung at the age of 16 when a finger was attacked and the whole hand became swollen and painful for hours. The second time when he was about 25 he was stung on the back of the hand; his whole arm swelled and his speech was blurred. The third time his lips and eyes closed almost immediately and he was unconscious for twenty minutes. He was then 35. Can he be successfully desensitized?

**A**—Extreme hypersensitiveness to the stings of wasps and bees can be eliminated usually for a period of years, by a series of specific injections. Few successful cases have been recorded in the literature, but details can be obtained from the classical work of Benson (*J. Allergy*, 1929, 1, 105, *Arch. intern. Med.* 1939, 64, 1306).

### Angina Pectoris

**Q**—Is spa treatment either in this country or abroad of any value in the treatment of angina pectoris which has not responded to prolonged rest and routine treatment?

**A**—If adequate treatment and rest at home have failed to achieve any improvement in a case of angina pectoris it is doubtful whether spa treatment anywhere will produce any good result. The travel and excitement might in fact do harm. On the other hand, emotional circumstances at home may induce attacks which can be relieved by an enforced holiday away from home, and this may also effect complete severance of the patient from preoccupation with business affairs. Moreover, where there is a strong higher centre element, and when reduction of weight is part of the treatment, the quiet and ordered calm and regime of a well-managed spa may secure results which could not be expected in the home environment.

### Children Travelling to the Congo

**Q**—What are the risks and what prophylactic treatment would you advise in the case of two children aged 4 months and 2½ years whose parents contemplate taking them to the Congo at an early date? Is malaria likely in children so young?

**A**—Children in the Tropics may be exposed to the ordinary risks of infectious disease, such as diphtheria, against which it is always advisable to immunize children, while in addition they may be exposed to more specifically tropical infections. Children going to the Congo should be vaccinated against smallpox and inoculated against the enteric fevers and yellow fever. Malaria is quite likely in young children, therefore they should be protected so far as is possible against the bites of mosquitoes by the use of mosquito nets, and they should also be given some suppressive antimalarial drug, in the case

of children aged 4 months and 2½ years, 10 and 20 mg of paludrine respectively every other day would probably be suitable suppressive treatment. If they are in a heavily infected sleeping sickness area the question of chemoprophylaxis by pentamidine might be considered.

### Yellow Fever in 1865

**Q**—How did the outbreak of yellow fever at Swansea in 1865 occur since the disease is spread by a type of mosquito not known in this country and the fever is not infectious man to man?

**A**—Once an *Aedes* mosquito becomes infected with yellow fever it remains infective for the rest of its life. The outbreak at Swansea in 1865 was due to mosquitoes brought by the *Hecla* from Cuba. These mosquitoes were either already infected in Cuba or were infected from infected members of the ship's crew.

### Glucose Injected Intravenously

**Q**—What is the fate of glucose injected intravenously? How and where does the body use it?

**A**—When glucose is injected into the blood stream it may cause a considerable rise in the blood sugar. If the latter is greater than 180 mg per 100 ml, the usual level of the threshold, some glucose will be excreted in the urine and lost. The glucose which remains in the blood will be taken up by the muscles and liver and laid down as glycogen. It is not possible to say how much is taken up by each of these two depots.

### Normal Blood Pressure

**Q**—What is the normal blood pressure in a healthy man aged 55? What variation can there be within normal limits?

**A**—A great deal depends on the circumstances under which the blood pressure is taken. When the patient is at home and at rest, and he knows the physician, basal readings will be obtained. Casual estimations under other circumstances will show considerably higher readings in the same patient. The normal basal blood pressure readings for an adult are usually taken to be between 105 and 145 mm Hg systolic, and 60 and 90 mm diastolic. Age plays only a slight part in determining blood pressure, which tends to rise slowly with advancing years. The upper limit for a normal man of 55 would be 155 mm systolic.

### Insect Bites

**Q**—What is the nature of the irritant injected by midges and clegs? What is the most effective antidote?

**A**—The irritation caused by the bites of midges and clegs is presumably due to the injection of their saliva, which usually causes irritation with blood-sucking insects. Little is known about the constitution of insect salivary juice, so that no specific remedies can be given. The secretion commonly contains foreign protein and may elicit an allergic response, so that the effects of bites vary widely in different people. Treatment can only be symptomatic.

### Mechanical Aids for Incontinence

**Q**—Would any mechanical contrivance help the distressing incontinence in a case of tuberculous cystitis?

**A**—Incontinence is not a usual complication of tuberculous cystitis, although frequency of micturition may be so great in the advanced stages of the disease as to simulate true incontinence. The only mechanical contrivance which such a patient could wear is a rubber urinal. This is an awkward and uncomfortable appliance, and many patients prefer a towel.

### Macrocytic Anaemia in Eunuchs

**Q**—Can you give particulars of a form of macrocytic anaemia occurring in eunuchs which responds to treatment with testosterone?

**A**—Experimental castration or hypophysectomy in rats leads to a fall in the red cell count and in the percentage of reticulocytes. Testosterone restores the latter, there being an immediate brisk reticulocytosis. Recently Watkinson and others (*Lancet* 1947, 1, 631) described two males with the Snapper-Witts syndrome (hypogonadism, alopecia, and anaemia associated with hypopituitarism). In one case a macrocytic anaemia

failed to respond to liver, and in the other a microcytic hypochromic anaemia failed to respond to liver or iron, nevertheless both responded to testosterone. In the former the testosterone was effective alone, in the latter the testosterone was effective only when given with iron.

### Nystagmus and Albinism

**Q**—A child aged 2 has had nystagmus from birth due to albinism. Strabismus and refractive errors have been corrected by glasses with tinted lenses since the age of 9 months. What treatment should now be given for these two conditions and what is the prognosis?

**A**—It is not uncommon for albinos to show physical defects other than lack of pigment. Nystagmus is, however, a constant feature in total albinism, and is believed to be secondary to maldevelopment of the maculae. The squint is likely to remain controlled by glasses. The nystagmus must be regarded as permanent.

### Intrathecal Penicillin

**Q**—What are the indications for administering intrathecal penicillin and what precautions are necessary to prevent possible complications?

**A**—The indication for the intrathecal administration of penicillin is meningitis due to an organism sensitive to penicillin but insensitive to the sulphonamide drugs. Meningeal infection by pyogenic cocci is thus the usual reason for such treatment. It is inadvisable to exceed an intrathecal dosage of 20,000 units daily, as there is danger of causing convulsions and a sudden increase in intracranial pressure. The most serious sequel of repeated intrathecal injections is secondary meningeal infection by such organisms as *Str. viridans*, *Ps. aeruginosa*, and coliforms which resist all forms of antibacterial treatment. Scrupulous asepsis alone avoids such complications.

## NOTES AND COMMENTS

**Apparatus for Mounting Stairs**—Dr T. PEARSE WILLIAMS, London, W1, writes: "I wonder if one of your readers could advise me whether there is any apparatus devised which would enable a patient with almost complete ankylosis at the knee joints and very deficient movement at the hips to mount stairs which have a double right-angled bend two thirds of the way up. To construct a lift would be a complicated business and very expensive."

**Joseph Thomas Digby**—Professor JOHN BOSTOCK, of the Department of Medical Psychology, University of Queensland, Brisbane, writes: "I have been engaged in writing the history of Australian psychiatry prior to 1850. In this connexion a Mr Joseph Thomas Digby and his wife left England in 1837 from St Luke's Hospital to become the first superintendent and matron of the newly erected Tarbryn Creek Asylum in New South Wales, Australia. Having finished their work in 1850, they were said to have left for England about 1851. We have no record of their life prior to their leaving England or after their departure from Australia. Mr Digby did yeoman work in psychiatry, and it would be greatly appreciated if any reader could give me any information concerning his life before and after his stay in Australia."

### Corrections

There was one omission in the article on "Ministers of Health" which appeared in the *Journal* of July 3 (p. 41). Sir A. S. T. Griffith-Boscawen was Minister of Health from October, 1922, to March, 1923.

In the leading article on the Prophit Survey (June 19 p. 1189) it was stated that the work was carried out by three Prophit scholars—Dr Ridehalgh, Dr Daniels, and Dr Springett. These workers were, in fact, the authors of the report "Tuberculosis in Young Adults," but it was not made clear that the results of work done by the fourth Prophit scholar, Dr I. M. Hall, were included in the report.

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. # SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY JULY 17 1948

## THE PLANNING OF NEW DERMATOLOGICAL DEPARTMENTS

On several occasions the Committee of the Dermatologists Group of the British Medical Association has discussed the provision of adequate accommodation for a modern dermatological department. Their interest in this matter has been stimulated by the knowledge that the efficiency of any department must depend to some degree on the adequacy of its equipment and accommodation. In their discussions they have borne in mind the fact that in some hospitals other departments may have to use the accommodation when the dermatologists are not working and it will be seen from the plan that a considerable part of the accommodation could be used by

medical facilities in an out patient department containing other specialist departments of comparable size.

It is appreciated that this plan will not suit in all cases and in this sense its use is limited. It may, for instance, be considered desirable that the whole of the diagnostic suite should be reversed and the senior dermatologist's consulting room should be adjoining the laboratory and private interview room or that the laboratory should be bigger. Such variations and amendments can be incorporated to suit particular and local requirements, and the plan has been conceived on the unit principle to make such adjustments possible.

So far as the type of plan is concerned, this has been designed to conform to a structural grid which would apply to a department designed as a floor of a multi-story building or alterna-

colleagues interested in other branches of medicine. The plan as presented is one which can be modified considerably to meet local conditions and local demands.

On behalf of the Committee I have to thank the Council of the British Medical Association for their permission to obtain technical advice in this matter, and Mr S E T Cusdin, OBE ARIBA AADip of Messrs Easton and Robertson who has devoted much time to the preparation of the following report. It is hoped that a model of the Dermatological Department will be made and will be kept at BMA House where it will be available for examination by those interested.

R M B MACKENNA  
Chairman Dermatologists Group

Report Prepared by Messrs. Easton and Robertson, Architects  
54 Bedford Square London WC1

We have pleasure in submitting Report No 2 on the basic plan for an out-patient dermatological department. The aim has been to produce a basic plan of a department for one senior dermatologist and four assistants and capable of diagnosing and treating 200 patients per day. It is assumed that the flow of patients would be controlled by an appointment system. The plan as shown is not deemed to include full teaching facilities for undergraduate and postgraduate courses but limited teaching facilities have been shown in connection with the diagnosis of patients in the senior dermatologist's consulting room. It has been assumed that this department would be working in conjunction with the normal complement of technical and

tively as a single-story structure. In the latter case the plan could be interpreted to fit into standard precast concrete frame buildings. The proposals are illustrated by a detail plan to 1/8 in scale and a schedule of the accommodation with sizes and the area of each room, is set out in the appendix.

The rate of flow of 200 patients per day in a department of this size does not call for a continuous one-way circulation. In order that the patients can be kept under supervision whilst attending either the diagnosis or treatment section, one patients entrance has been provided immediately between the two sections. The patients on entering the department would register at the records office and the record forms would be passed for completion to the dermatologists and the staff. It is envisaged that a system would be evolved for the rapid screening of the patients by a doctor to decide to which of the dermatologists they are to be directed. It is visualized that the largest group of patients is likely to accumulate in the diagnostic section the main waiting space has therefore been planned in this area and has been designed in an informal manner on the lines of the recent examples on the Continent and not in the rigid institutional manner so common in existing out-patient departments. After examination by the doctor the patients would be free to pass to the dressing-rooms for bandages or to any other of the treatment rooms.

The almoners office is planned at the patients entrance which is also the exit in order that she may interview the patients either on entering or before leaving. It might be considered desirable in certain cases to link the treatment section

of the out-patient department to the in-patient accommodation in the hospital. This connexion is shown directly off the main corridor of the treatment section of the department. The main lavatory accommodation for patients is by the main entrance. There is a separate entrance for the medical, nursing, and administrative staff, complete with locker rooms and lavatory accommodation.

#### Detail Planning

The department divides itself into three main sections—viz., (a) nursing and administrative, (b) diagnostic, (c) treatment.

##### (a) Nursing and Administrative

The accommodation for the sister and nursing staff has been placed centrally in the plan in order that they may supervise all the activities of the patients and be in direct access with the medical and treatment staffs. A separate office has been provided for the sister for private discussions with the doctors, nurses and patients. The records office is shown along one side of the main waiting space, with a hatch into the almoner's office and into the departmental clerk's office. A station is also provided here for the medical officer concerned with the preliminary screening of new patients. The records office would be separated from the main waiting space by a glazed screen 6 ft 6 in. high in which there would be openings at which the patients would register and draw the necessary documents.

##### (b) Diagnostic

The diagnostic section consists of a large consulting-room for the senior dermatologist, and four separate rooms *en suite* for his assistants. All these rooms are intercommunicating. The main consulting room has two examination rooms and immediate access to a dark-room, in which would be installed the Woods appliance. This dark-room is also available for the assistants. The consulting-room would be fitted with a lavatory basin, a blackboard, and a work and demonstration bench. It is laid out so that the senior dermatologist would be able to see his assistants through the glazed screens and to have his patients in the full light from the windows, and at the same time be able to address a small group of students on his right-hand side.

Each of the examination cubicles should be fitted with an examination couch, chair, and necessary arrangements for the hanging of patients' clothes.

Each of the assistant doctors consulting rooms is fitted with a lavatory basin, small work-bench and notice-board. The room is laid out so that the patients are under the full light from the windows. An examination couch, chair, and hook for patients' clothes are shown as part of normal furniture of these rooms. A small laboratory and private-interview room are available for any of the medical staff to assist in their consultations.

A clinical photographic room has been provided with a small undressing cubicle for patients. The fittings would include the necessary special photographic lighting platform, behind which there would be arrangements for changing the texture of the background, and a small work-bench fitted with laboratory sinks, storage cupboards, etc.

##### (c) Treatment

The treatment section consists of minor operations theatre, treatment-and-dressing room, on one side of the corridor, and the x-ray and ultra-violet-ray rooms on the other.

Adjoining the minor operations theatre and the treatment-and-dressing room are six undressing-rooms for patients. Facilities are available in the minor-operations room for surgeon's scrub up, and immediately off the theatre there is a small sterilizing room. The treatment-and-dressing room has been designed with a sterilizing and preparation recess for the nursing staff, and four cubicles for patients, the cubicles have been provided so that a number of patients can be receiving treatment concurrently. Each cubicle is designed with a couch, chair, and clothes hooks. In the other part of the treatment room is space for the laying-out of dressings, trolleys, etc.

The x-ray suite consists of separate rooms for superficial and contact therapy and for the Grenz-ray apparatus. Each of these rooms has an undressing cubicle for patients. The fittings to the room include a lavatory basin and work-bench. The

ultra-violet-ray room consists of three cubicles for the treatment of patients and a bathroom complete with shower, etc. and space for preparation, fitting, and storage of the apparatus. There is a separate suite of patients lavatories in the treatment section.

#### Summary of Accommodation

The total area of the out-patient department is 8,460 square feet, made up as follows:

	Area in Square Feet	Percentage of Total
Nursing and Administrative	702	8
Diagnostic	2,007	24
Treatment	2,181	26
Net Area of Department	4,890	
Circulation, including waiting space, lavatories, etc.	3,570	42
	8,460	100

#### APPENDIX SCHEDULE OF ACCOMMODATION

	Size in Feet	Area in sq ft
<b>(a) Nursing and Administration</b>		
Nurse's Station	12 × 9	108
Sister's Office	12 × 9	108
Almoner's Office	12 × 9	108
Records Office including Doctor's Desk	30 × 9	270
Clerk's Office	12 × 9	108
Total		702
<b>(b) Diagnostic Section</b>		
Senior Dermatologist's Consulting room	24 × 18	432
2 Examination Rooms, each	9 × 6	108
Dark-room	9 × 6	54
Clerk's Desk	9 × 6	54
4 Assistant Dermatologists Consulting rooms, each	18 × 12	864
Private interview Room	13 × 9	117
Laboratory	18 × 9	162
Photographic Studio	18 × 12	216
Total		2,007
<b>(c) Treatment</b>		
Minor-operations Theatre	18 × 18	324
Sterilizing Recess	12 × 8	96
3 Dressing-rooms, each	5 × 3	45
Treatment-and-dressing Room, including 4 cubicles	30 × 18	540
Sterilizing Recess	12 × 8	96
Superficial X-ray Room	18 × 12	216
Contact-therapy Room	18 × 12	216
Grenz Ray	18 × 12	216
Ultra-violet ray Treatment Room, including bathroom and 3 cubicles	24 × 18	432
Total		2,181
<b>(d) Circulation</b>		
Corridors, waiting space, lavatories, locker-rooms, etc.		3,570
Grand Total	8,460 sq ft	

#### TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

**Metropolitan Borough Councils**—Fulham, Hackney, Poplar

**Non County Borough Councils**—Dartford, Radcliffe (limited to future appointments), Tottenham, Wallsend

**Urban District Councils**—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Portlaid, Redditch (restricted to new appointments), Tyldesley

## Annual Meeting Notes

### ACCIDENT AND OPPORTUNISM IN RESEARCH

Sir Henry Dale's Popular Lecture

Almost the last event of the Annual Meeting was the Popular Lecture, which was delivered by Sir Henry Dale, O.M., in the Large Examination Hall, Bene't Street, Cambridge, on Friday evening, July 2. The President of the Association, Sir Lionel Whitby, was in the chair.

Sir Henry Dale began by saying that accident and opportunism must go together if accident was to be anything but a nuisance in research. Perhaps it was essential that a man should know whether what appeared to be an accident—a phenomenon presenting itself inexplicably—was a nuisance and the result of a trivial error or whether it offered the possibility of a discovery of real importance. It had been said that accidents happened only to those who deserved them. Accident had played some part, though not so large a part as popular rumour suggested, in the great discoveries of the 'nineties by Roentgen and Becquerel which did so much to launch physics into the new era in which we were living to-day.

Medical research might be said to be a recent development, beginning to get on its way at the beginning of the present century, but earlier than that advances were made by great physicians who used to the full the opportunities they encountered by accident in their practice, observing the regular recurrence of symptoms or the association of signs and symptoms with certain conditions which others had passed unnoticed. Here Sir Henry Dale referred to the work of Jenner which laid the foundation of vaccine therapy, and the discoveries of Pasteur out of which the science of bacteriology grew.

Sir Henry Dale next turned to the work on hormones and vitamins. The beginning of scientific endocrinology might be found in the brilliant use which physicians in the middle of the nineteenth century were making of the opportunities presented to them by the accidents of practice for correct observation at the bedside and in the post-mortem room. In considering the early recognition of the vitamins the lecturer mentioned a name famous in Cambridge, that of the late Frederick Gowland Hopkins, and spoke of his researches and those of his disciples, and their use of what appeared to be accidental findings, which gave shape to modern biochemistry. He also mentioned how a train of accidents brought about the development of Ringer's solution, the discovery of adrenaline, and the finding by accident of acetylcholine while search was being made for something else. He described the researches in which he himself had been concerned with regard to histamine. It took many years before it was established that histamine was a natural constituent of most of the cells of the living body, normally harmless, but released to produce its characteristic effects if the living cells came into contact with some substance to which they had become abnormally sensitive or allergic. Finally he referred to the discovery of penicillin.

"Many other instances could be mentioned," said Sir Henry Dale in conclusion, "and there must be innumerable cases of which we know nothing because they have never been recorded. I hope, however, that you will not think that accident is a principal factor in research of any kind and in medical research in particular. Accidents of this sort do not often happen to the merely fanciful speculator. They happen to the men who, while continuously busy, do not close their minds to matters outside their principal aims and objects, and who keep their interest and attention alert for the unexpected. I do not believe that any research work of value is done without a great deal of hard, systematic, and conscientious toil, nor do I think that mankind would have been left in permanent ignorance through default of the accidents which precipitated great discoveries."

The President remarked on the fascinating interest of the address and asked the audience to signify their thanks, which they did with acclamation.

*We hope to publish Sir Henry Dale's Lecture in a subsequent issue of the Journal.*

### MEDICAL MISSIONARY BREAKFAST

Another of the Annual Meeting events which made a pleasing reappearance was the breakfast arranged by the Medical Prayer Union. This was held at the Pitt Club, Cambridge, on July 2. The Vice-Chancellor, who presided, said that he had always regarded the partnership of doctors and clergy as perhaps the most promising outcome of that reunion of science and religion for which some of them had been working.

An address was given by Sir Henry Holland for so many years in charge of the Quetta Mission Hospital, Baluchistan, on recent events in India. He said that the population movement in India last year was the biggest mass evacuation that had ever taken place. Some ten million people had been on the move. Emergency surgery was carried out extremely well by mission hospitals and civil hospitals in the various districts, but the aftermath of the massacres was almost more tragic than the murders themselves. The refugees had been herded together in camps containing 200,000 to 300,000 people, some had walked 600 miles trying to find shelter. The appalling condition of the camps was no fault of the Government, it was almost impossible to cope with the situation. Dysentery was nearly universal, cholera was very much in evidence, and the effects of starvation were everywhere pronounced. The medical missions stepped into the breach and relief units were formed which went to all the big centres. The Red Cross sent a large unit out from Great Britain, the Government machine got to work, and gradually the situation improved.

Sir Henry Holland added that far-reaching plans had been made for a medical and hospital service in India and for the care of the blind, it would be particularly the responsibility of European doctors to see that the standards of hospital care and of medical education were maintained. An enormous amount of material for study was available, and India offered great opportunity not only for enhancing the reputation of British doctors in India but for winning the soul of India for Christ.

### ROMAN CATHOLIC SERVICE

A service was held at the Roman Catholic Church, Hills Road, on July 1, when an address was given by His Eminence Cardinal Griffin, Archbishop of Westminster. After the address Benediction was given.

Cardinal Griffin said that the future of medicine in this country would depend upon whether doctors considered their profession as a trade or as a vocation. A man traded for material gain, he followed a vocation for the service of others. I should rather like to stress this point to-day, the Cardinal continued, "because I see from the papers that your conference has been discussing whether or not doctors should form themselves into a trade union. The use of the term 'trade union' as applied to the medical profession may easily create a totally wrong impression. Priest and doctor have very much in common. We are both concerned about the welfare of human beings, you mainly about their temporal well-being and we about their eternal life. In many cases, and especially in cases in which there is mental illness, we need each other's help. I always like to feel that we are moved by the same desire to help others who are in need of our help, and that we aspire to the same high service—in fact, without such high ideals it would be difficult to explain the devoted lives of many doctors."

There was always a danger that the patient might be considered merely as a case—merely as a heart, or a head, or a kidney, or an appendix, and not as an individual with personality, capable of becoming the son of God. They were often told that there was a conflict between science and religion. Such conflict existed only in the minds of those who misunderstood much of one or of the other or of both. Science was coherent systematized knowledge based on observation and verified by experiment, and medicine, which was a science, took note of all that should come under the observation of science and could be exactly recorded. Religion, on the other hand, was the sum total of the knowledge of God and of divine things. "Always remember that you are dealing with a patient who is both body and soul, who has divine rights and privileges, and in proposing or applying any remedy never forget those rights and privileges which are his."

Cardinal Griffin touched upon the ethics of abortion. "The child in the womb has an equal right to live with the mother, and

the best medical practice will prescribe a remedy which will safeguard the lives of both mother and child." He also mentioned euthanasia. "Do not let us give way to sentimentalism—the sort of sentimentalism which would recommend the abolition of the death penalty for the murderer and would recommend the death penalty for an innocent and helpless patient. The doctor's duty and privilege is to save life, not to destroy it, and if destruction were one day recognized as part of his duty he would rightly deserve to lose any confidence which the public places in him."

In conclusion he reminded the congregation that both in home and hospital treatment the Catholic Church had been in the forefront in the welfare of the sick. Long before states interested themselves in these matters the voluntary service of the Church through the monks and nuns set an example unparalleled in the history of medicine.

At the close of the service a reception was held in the adjoining Houghton Hall.

## PATHOLOGICAL MUSEUM

The Pathological Museum which was visited by many of those attending the Annual Meeting at Cambridge, was divided into four main sections. The historical section included a collection of maps, prints, and photographs assembled in the department of pathology by Dr G S Graham-Smith. They showed the development of the Cambridge Medical School and more particularly of the department of pathology. The new museums were built on the site of the old Botanic Gardens and some beautiful specimens of plants of pharmaceutical interest were added to this section. The enormous growth of the department, which now has offshoots in the Field Laboratories, the Department of Animal Pathology, the Papworth Village Settlement and the Cambridge Research Hospital, now the Strangeways Research Laboratory was illustrated by photographs, aerial photographs, and charts and there was shown also a list of the distinguished professors of pathology.

The Pathological Museum contained 30 specimens from cases of sudden death associated with cardiovascular disease collected by the late Lt-Col A Whitmore. Among the recent additions to the Museum was an acardiac monster whose twin was normal apart from a facial paralysis. The outstanding demonstration in this section was a series of lungs cut in complete sections and mounted on paper or in fluid in a thin case of "perspex." The paper sections were in their natural colour, and the wet mounting was done in hydrosulphite solution. The collection demonstrated clearly the different changes associated with simple pneumoconiosis with a focal distribution of dust lesions, and in infected pneumoconiosis with massive fibrosis. Bronchiectatic lungs, tuberculous lungs, and tumours of the lungs were all superbly shown. The same method has been used for other organs and several cerebral tumours were displayed with a clear picture of their orientation and spread. This method has great advantages in the saving of materials and storage room.

Dr A B Bratton demonstrated the thymic changes in myasthenia gravis and Dr P L Mollison showed the technique of Rh testing, some typical blood films, and the apparatus for exchange transfusion. Dr J N P Davis (Uganda) showed several hearts obtained from natives dying with congestive heart failure. The lesions were mixed endocardial and myocardial with a moth-eaten appearance of the muscle which showed hydropic degeneration microscopically. The aetiology was not known, but there was probably a nutritional deficiency, though not of thiamin.

In the dermatological section the newer methods of demonstration were used and there were many excellent enlarged colour photographs of typical lesions. Transparencies from Dr Anderson (Aberdeen), Dr Silcock (Leicester), and Dr H J Twiston Davies (Manchester) were also an advance on older methods of recording. Coloured drawings depicted such varied conditions as Paget's disease of the nipple and a "turban tumour." The best colour prints were shown by P G Hennell, of the Metal Box Co., Ltd., whose collection would make excellent teaching material. Among a host of pictures of sensitization dermatitis an outstanding example of lipstick dermatitis with a positive patch test was shown by Dr E Ritter (Lincoln). Rodent ulcers, epitheliomata, and naevi were numerous, but so were the rarer conditions of Kaposi's varicelliform eruption and mycosis fungoides.

The Pharmaceutical Society's exhibit was an elegant demonstration of careful preparations of penicillin and other materials.

Methods of assaying penicillin were also on view. A home-made pH-meter was used for checking the final pH of buffered solutions made for eye drops, etc. The complete process from the plant to the crude drug and to the purified active principle was also well set out and illustrated by digitalis and curare. The simple and effective machines for making emulsions and tablets were constantly in action.

## FACULTY OF OPHTHALMOLOGISTS

The following have been elected as officers of the Faculty for 1948-49: *President*, Sir Stewart Duke-Elder, *Vice-President*, Mr J J Healy, *Honorary Secretary*, Mr Frank W Law, *Honorary Treasurer*, Mr O M Duthie. Mr J H Doggart has been co-opted to the Council of the Royal College of Surgeons of England for 1948-49 as the representative of the Faculty.

Representatives of the Faculty have met representatives of the Ministry of Health to discuss several points connected with the supplementary ophthalmic service, including the use of drugs by opticians. The Ophthalmic Benefit Approved Committee have recently authorized the use of certain drugs by opticians in national insurance work. The Faculty's representatives have made it clear that they are strongly opposed to the use of drugs by opticians and the Ministry's officials, while not committing themselves, have suggested that for the supplementary eye service no regulations about the use of drugs by opticians should be laid down, but that a commission which has been appointed to consider registration of opticians should make a decision on the matter. The standard of vision required on examination by opticians and the need for a report to the patient's general medical practitioner if that standard was not attained have also been considered. The Faculty's representatives put forward the opinion that 6/6 for each eye examined should be the standard. The Ministry's officials considered that this would be too high a standard for incorporation into regulations, and agreed that guidance on this matter should be given in a handbook to be issued to opticians, the relevant portion being first submitted for the Faculty's comments.

The question of whether ophthalmologists should see patients in their own consulting-rooms under the supplementary ophthalmic service has been discussed by the Council. It is the policy of the Faculty that State patients should be seen in clinics under the supplementary service or in hospital clinics under the permanent service, and that this latter service should be inaugurated as soon as possible, because it is the Faculty's view that no supplementary ophthalmic service clinic should be held in hospital. Where there is no clinic available it will presumably be unavoidable for patients to be seen in private consulting-rooms under the supplementary ophthalmic service, though it is likely that this practice will result in a destruction of private practice.

Nominations for the ophthalmic services committees of local executive councils throughout the country have been discussed with an assistant secretary of the British Medical Association. Various fusions, modifications, and additions have been agreed which will all appear on the final list.

## ROYAL MEDICAL BENEVOLENT FUND

The Annual General Meeting of the Fund was held on June 29 and the following honorary officials were re-elected: Lord Webb Johnson, *President*, Dr C L Batteson, *Honorary Treasurer*, Mr Victor Riddell, *Honorary Secretary*.

The Honorary Treasurer, presenting the balance sheet and accounts for the year, said that it was a great pleasure to record an increased subscription income, in fact, the figure of £20,79 was a record. In addition there were some special donations amounting to £1,330. The financial improvement was due partly to the fact that some medical bodies whose activities had ended had handed over their credit balance to the Fund. They could not look forward, however, to future gifts from those donors, and they hoped the loss would be made good by other well-wishers.

Mention must be made of the wonderful response to the President's Christmas appeal, which constituted a further record. It enabled them to distribute Christmas gifts of £5 each to all the regular beneficiaries—a sum amounting to £2,300, and to carry forward a small sum to 1948.

Last year he asked subscribers to give additional help to the Fund, without further cost to themselves, by signing a seven-year covenant. No fewer than 343 new covenants had been signed. It might be an encouragement to other subscribers to know that over 1,150 covenants had now been signed. These facts to some degree accounted for their larger income, but there was another factor of even greater importance. He was convinced that the whole profession was realizing more and more the absolute necessity of the Benevolent Fund, and consequently there was an ever increasing willingness by many to come forward and help in the work by becoming annual subscribers. Since the last report no fewer than 143 newly qualified members of the profession had become subscribers.

"My Report, as Treasurer, would not be complete without recording the wonderful generosity which is shown to us by the Medical Insurance Agency. During the year we received a magnificent cheque of £2,520 17s 3d. This sum being paid under covenant enables the Fund to recover income tax, thereby vastly increasing the value of the gift. There are many others who have shown us great kindness, but they are too numerous to mention by name, but our thanks are very sincere to the Committee of the B.M.A. Charities Trust Fund for their generous allocations each year.

"I make a special plea for subscriptions and legacies for our new venture—namely, 'Westmoreland Lodge'—which is the residential house for some of our aged beneficiaries, because we wish to extend this side of our work. All cheques and legacies should be drawn to the credit of the Royal Medical Benevolent Fund, but those desiring their contributions to be towards our residential house, or perhaps, in the future our residential houses, should signify their wish. Finally, I ask all kind subscribers to help us in our office work by (a) using banker's order, (b) signing seven-year covenants, (c) sending subscriptions early in the year."

## MATERNITY MEDICAL SERVICES

### PAYMENT WHERE ARRANGEMENTS WERE MADE BEFORE JULY 5

The Minister of Health has considered the question of the arrangements to be made and the payments due where midwifery cases were booked before but the confinements are not expected until after July 5 (or occurred shortly before July 5). The Ministry states that a doctor on the special obstetric part of the medical list will be able on July 5 to make arrangements for carrying on and for providing maternity medical services to the patient under the new Scheme (using Form E.C. 24 suitably adapted), and in that event he will be entitled to appropriate remuneration from the council for services given on or after the date on which he accepts the patient, for services given before July 5 the doctor would look to the patient for payment. A doctor not on the special obstetric part of the medical list but who is attending a patient on his own general medical services list will also be entitled to make similar arrangements (using Form E.C. 24A suitably adapted), and the position as regards payment is similar. In neither case would the doctor be entitled to charge the patient herself for services given on or after July 5 if the patient is on his own list (or the list of a partner or assistant).

The payments will be as follows. Column 1 refers to the doctor who is on the special obstetric part of the medical list, Column 2 to the doctor who is not on the obstetric part of the list but is attending a patient on his own general medical services list.

1 Doctor on Special Obstetric Part of Medical List	2 Doctor on General Medical Services List Only
Confinement on or after July 5	
Period II fees of 4½ gns plus 10s 6d for each antenatal examination after July 5 with maximum of 7 gns	Period II fees of £3 7s 6d plus 7s 6d for each antenatal examination after July 5 with maximum of 5 gns
Confinement before July 5	
Where confinement takes place	Where confinement takes place
(i) within one week before the new arrangements are made 3 gns	(i) within one week before the new arrangements are made 2 gns
(ii) within 2 weeks before the new arrangements are made 2 gns	(ii) within 2 weeks before the new arrangements are made 1½ gns
(iii) within 6 weeks before the new arrangements are made 1 gn	(iii) within 6 weeks before the new arrangements are made 15s

## SUPERANNUATION IN N.H.S.

*The following statement on the option open to medical practitioners holding life assurance policies and on the extension of pensionable age for practitioners has been issued by the Health Service Superannuation Division of the Ministry of Health.*

It was recognized when the National Health Service (Superannuation) Regulations, 1947, were made that many doctors and dentists (referred to here as practitioners) who come on to the lists of executive councils at the inception of the National Health Service would already be committed to paying premiums on insurance policies taken out to provide for themselves on retirement, or for their wives or dependants in case of death.

The option enabling a practitioner who is already adequately covered by insurance to contract out of the Health Service scheme is available *only* to those doctors and dentists who (a) hold a contract of insurance or policy of insurance with a life assurance company on July 5, 1948, and (b) are on the list of an executive council on that date. The choice lies between (a) becoming liable for contributions and eligible for benefits under the Health Service scheme and (b) remaining outside the scheme and receiving an amount equal to 8% of his "net" remuneration (i.e., the payments for general medical or dental services less a percentage for practice expenses) towards the maintenance of approved insurance policies.

The exercise of the option will be subject to the following conditions, discussed with representatives of the medical and dental professions, intended to secure that the payments shall be related to current policies giving cover broadly equivalent to that in the Health Service scheme.

(a) The policies must be endowment assurances or deferred annuity policies.

(b) The policies must not mature at an earlier age than 60. Where a policy would under its original terms have matured before age 60, it can be recognized if its terms are modified so that it matures at or after age 60.

(c) (i) The premiums (or total premiums) must not be less than £150 per annum. (ii) Alternatively, if the total annual premiums on existing policies are less than £150 per annum but not less than £50 per annum, these policies will be recognized on condition that the practitioner takes out forthwith a further policy which will bring the total premiums to at least £150 per annum on policies satisfying the conditions set out in (a) and (b) above.

(d) The policies must not be assigned to any other person, or surrendered before maturity.

(e) Payment by the Minister of an amount equal to 8% of the practitioner's remuneration will continue only so long as the premiums on the policies continue to be payable.

(f) The policies must be produced for inspection on a request made to the practitioner by the Minister or by the executive council on his behalf. Alternatively, a statement from the assurance company on the nature of the policies may be submitted.

(g) Premium receipts must be submitted to the Minister or to the executive council for examination within one month after the date on which each payment of premium falls due.

Before deciding whether or not to exercise this option a practitioner will wish to weigh the relative advantages of the courses open to him. Attention is therefore invited to the booklet 'Superannuation Scheme for those Engaged in the National Health Service—An Explanation,' a copy of which will be supplied free of charge by the executive council. Sections B and C of that booklet outline the contributions and benefits, and paragraphs 1, 5, 7, 16, and 25 deal with special conditions applicable to practitioners who are subject to the scheme. Paragraph 16 of the booklet shows how benefits are calculated in the case of practitioners and should be borne in mind when reading the other paragraphs in Section C.

A practitioner who can satisfy the conditions stated here and who wishes to rely on his insurance policies and not come into the superannuation scheme must send a written request to his executive council within the period from July 5, 1948, to October 4, 1948. A form for this purpose can be obtained from the council.

### Extension of "Pensionable Age"

"Pensionable age" is the age at which contributions cease to be payable and service ceases to count under the regulations. This is normally 65 years of age, but a practitioner who has attained the

age of 60 can apply to the Minister of Health for an extension to a later age, not beyond the age of 70. This does not affect the age at which a practitioner may retire with benefits under the Scheme, this is on or after age 60, with a pension if 10 years' service has been completed, or with a lump sum retiring allowance after five years, and retirement can be after "pensionable age". There is no time limit for applying, and any practitioner now under 60 may apply when he reaches that age.

The extension will be of particular value to those practitioners who enter the National Health Service late in life. For instance, it will enable practitioners of just under 60 years of age at entry to put in the 10 years' service required to qualify for a pension on retirement. It would also give a higher rate of incapacity pension in the case of a practitioner who is over 45 years of age when he enters the Service (see paragraph 11 of the booklet). In considering an application the Minister will consult the practitioner's executive council, asking them to obtain the views of the local medical committee or the local dental committee as the case may be. The Minister may also require to be satisfied as to the health of the practitioner. If an extension of pensionable age has been allowed it cannot subsequently be varied.

Applications for an extension of pensionable age should be addressed to the Ministry of Health, Health Services Superannuation Division, 28, Princes Gate, London, S W 7.

## Correspondence

### The Changing Face of Medicine

SIR,—In his Presidential Address before the B.M.A. Sir Lionel Whitby (July 3, p. 2) speaks of the economic factor as having been "potent in hastening the inevitability of a State medical service", and he then gives "a few facts and figures" which "will serve to establish the point". I feel strongly that Sir Lionel has done no more than show that a few illnesses are so expensive that most of the sufferers need financial assistance from the State, but he has certainly not shown that this makes a State medical service inevitable. Most of the ills to which man is heir are dealt with more rapidly and cheaply than ever before, and it would have been only equitable if Sir Lionel had given a credit column as well as a debit one in his accounts.

"A few facts and figures will serve to establish the point". Gonorrhoea can be cured so quickly that most sufferers need lose no time from their work, pneumonia no longer causes months of ill health, meningococcal meningitis has lost most of its terrors, and even surgical operations, expensive though they may be, do not as a rule cause the prolonged periods of absence from work that they used to do. But it must be admitted that if every pyrexia of uncertain origin is to be the subject of intensive investigation the cost will be very great, and most of the patients will have recovered long before the laboratory investigations have been completed.

There has arisen in many minds, both medical and lay, a remarkable confusion between research and the practice of medicine. For instance, the clinical researcher is, very properly, more interested in the genesis of symptoms and signs than in the diagnosis and treatment of the individual sufferer, but that is no reason why every case should be investigated in such detail. What earthly reason could there be for wasting time and money in carrying out a daily reticulocyte count on every case of pernicious anaemia during the early stages of treatment, important though such a procedure is in testing the potency of liver extracts? How, in fact, is it possible to justify the great majority of investigations that are carried out in the common maladies? I would assert that it is impossible to do so, and that the only reason for doing them is because some patients, as the result of "an enormous expansion of the Press during the past 50 years," have come to believe that they should be the directors of their own treatment.

Surely Sir Lionel would not assert that the innumerable laboratory examinations demanded by house physicians (because they fear their chiefs' wrath) are really necessary. It is our duty to see that the cost of illness is kept as low as possible, but who can deny that the tendency in recent years has been exactly the opposite?—x-rays for record purposes, blood counts for the sake of completeness, Wassermann tests because a few people have syphilis, although most have not, complicated and time-consuming tests of kidney function, when simple ones would serve the practical physician's purpose and,

last but not least—the latest extravagance—clinical photography for the purpose of filing with records, most of which will never be looked at again.

SIR, if we are sensible, a State medical service is not, even now, inevitable. True enough the N.H.S. is here, but that is not *sensu stricto* a State medical service. We all have to pay for it, but we do not all have to use it, and, if we make sure that our patients are not subjected to endless unnecessary tests, we shall find that many of them will prefer the old method of continuing to pay for what they get as and when they require it. The persistence of private and public schools in spite of a State educational scheme should serve as an example to us—I am, etc.,

London W 1

A. PINEY

### Reduced Incomes

SIR,—Can it be that the Association is really going to accept the terms offered by the Minister? We have been entertained by much talk about the purity of our principles and how far our spokesmen have succeeded in securing their admission by reluctant bureaucrats. That is all very well, but so far we of the rank and file have heard nothing definite about the attitude of the Negotiating Committee to the financial proposals and are left considering how on earth we are going to carry on if our future remuneration is to be at a standard rate of fifteen bob (and sixpence) a nob.

Circumstances vary within such wide limits between place and place and between individual practices that it would seem to be impossible to secure fair play by enforcing a rigidly uniform system of payment throughout the whole Service. As usual in these days, when, regardless of the laws of biology, all men and women must be considered simply as units, the rules have been formed as if all the people in this country were herded into great cities with populations of hundreds of thousands. Even on this reckoning the proposals of the Minister are designed to encourage all that is worst in the practice of medicine. The only way open to the earning of a reasonable living is to take on patients by the thousand without any regard to what sort of treatment can be given to them. It is ridiculous to pretend that any one man can give anything like adequate attention to 4,000 persons, men, women, and children. The only way one could hope to cope with such a multitude would be to push off anyone who is really ill to the nearest hospital, in other words to pass the buck to someone else at the earliest opportunity.

I have practised for a number of years in a seaside health resort with a population of 22,000. The Minister would have us believe that a force of four or five doctors should be sufficient to deal with all the needs of such a community, yet we have found that the work has always been sufficient to keep 12 to 15 doctors in full employment. We are also on the staff of our local hospital and follow our patients through all their illnesses with the help of visiting surgeons and physicians. Within our limits we carry out, I think quite successfully, a number of emergency major operations and all minor surgical procedures ourselves. This I admit has added enormously to the interest of general practice and has acted as a spur to keep us constantly on our toes. The place being what it is, many of our patients are either old or invalid and consequently require considerably more attention than an equal number of the young and fit. The Minister apparently takes no account of this but relies on the simple counting of heads in the assessment of the value of our service. It is true that an offer is made to create a staff fund of £25 per bed, based on the average number of occupied beds per annum, but if this is intended as compensation for the number of hours spent in the operating theatre giving major anaesthetics, carrying out post-operative treatment, and dealing with casualties one can only describe this offer as farcical.

The cheap press has given the public the idea that in the new Service all doctors will be enjoying incomes of £3,000 a year and upwards, and the powers that be in the Association have not yet so far as I am aware taken any steps to enlighten the people on the facts of the case. It is all very well saying that we practitioners must now do all we can to make the new Service a success. I submit that the first requisite for the attainment of that worthy object is to ensure that those who have to work the Service are happy and contented. Until that object is attained, and it cannot be so long as many of us are faced with a steep decline in our incomes, one can only view the future with the greatest alarm and despondency—I am, etc.,

Bridlington

C. J. GORDON TAYLOR

### Superannuation Scheme

SIR,—I feel disgusted at the way the profession has been browbeaten into a scheme which the majority view with alarm and distrust. Not only have we to serve, but furthermore we have to contribute to an insurance scheme from which we get little or nothing in return. We have accepted with complacency an arrangement whereby our homes have become the public's health centres for wives and families slaves, and our relative remuneration falls. Now we have a superannuation scheme (which requires the comprehension of a financial wizard) thrust upon us to deplete still further our already rapidly dwindling incomes.

You may be assured that if united resistance is not forthcoming further burdens will be added. Surely the time has now passed for ever when a free man could think and act according to his own judgement as to how he should arrange his affairs to best suit his wife and family's future. We are reduced to following the herd. Initiative is destroyed. The profession will live to rue the day it sold its heritage—I am, etc.,

S. Withport, Lancs.

BERNARD SAMUELS

SIR,—Medical practitioners must compulsorily take part in the superannuation scheme of the NHS, except that under certain conditions (at present unknown) there is an option to practitioners holding life assurance policies to remain outside the scheme by giving notice in writing within three months of July 5.

From 1932 onwards many practitioners like myself contributed to the pension scheme for national health insurance practitioners sponsored by the Insurance Acts Committee. The insurance companies concerned naturally will be interested in retaining business, and any opinion from that source must be regarded as biased.

I hope the appointed trustees, on learning the contents of the promised leaflet SDD, will publish their considered opinion in our columns. Practitioners with other forms of life and endowment assurance would equally welcome guidance. In particular, practitioners who have taken policies to cover loans against purchase of practices are vitally concerned. Already paying large premiums, are they to pay a further 6%, or may they opt out, and, if so, is it in their best interest?—I am, etc.,

Birmingham

THOMAS J. CRONIN

An abstract of leaflet SDD appears at p. 47 of the Supplement—Ed. BMJ

### The Greatest Safeguard

SIR,—For many years I have been a loyal supporter of the BMA and recently have been present at Special Representative Meetings on the National Health Service Act for the past two years. Up to April, 1948, I was quite satisfied with the way in which negotiations were being conducted on behalf of the profession, though I had slight misgivings over the omission of any real assistance on the terms of remuneration. I thought, however, that once our principles were conceded the negotiators would turn their attention to this point before advising the profession to accept service.

I was profoundly shaken in April by the hurried plebiscite, which seemed to me quite unnecessary in view of our then existing position in relation to the Minister of Health and the result of the previous plebiscite. I attended the Special Representative Meeting on May 28, when a majority showed that they disapproved of the holding of the April plebiscite.

Representatives were told at this meeting that the decision to hold the plebiscite was made by a majority of the Council, but no one present succeeded in ascertaining either by what majority in the Council the decision was made or which members of the Council voted for or against the decision. A few members of the Council had the courage to state their views, which is greatly to their credit, but the majority remained silent.

It seems to me now that those members of the Council who voted for holding the April plebiscite should resign in view of the resolution passed at the May Special Representative Meeting. My reason for saying this is because I feel more than ever that a strong and united BMA and a Council completely trusted by its members is the greatest safeguard the profession can have and the only protection against encroachment on its liberty and freedom by the Government now or in the future.

Another disquieting feature is the undue emphasis which the BMA has allowed to be placed on the pronouncements of the Royal Colleges during the negotiations. These Colleges only represent a small portion of the profession and do not in any way or at any time, pretend to consult the views of the many thousands of members and licentiates of the Colleges who in this case have been vitally affected by the Presidents' stated views.

It is true that Lord Horder's motion criticizing the Council of the BMA was defeated by a large majority. This, I think, was due to a feeling that if the complete Council resigned as a result of passing this motion the BMA would be split at a most critical time.

Thousands like myself have now been forced to enter this Service, which we dislike but which we feel could have been made very satisfactory both to patient and doctor, by the financial threat of loss of compensation if we did not enter by July 5. Surely our negotiators should not have advised us to go into this Service when this very unfair weapon was being held at our heads—I am, etc.,

Eastbourne

P. W. MATHEW

### The Public Not Informed

SIR,—So the trouble has started 'already'! This morning—July 2—I opened my *BMJ* and read the Minister's honeyed message on p. 1, later in the day I opened my evening paper and read the Minister's outburst in the House when he blamed the BMA for the sign-on muddle. Meanwhile what has happened to recommendation C passed at the SRM on May 28, "That the public be adequately informed that the profession cannot hold itself responsible for the Government's promises"? So often we have been told of the stacks of propaganda provided by the Public Relations Department which lie at Tavistock Square, yet none of it seems to escape to the outside world for which it was designed. True, Dr. Dain said at Cambridge that half a million leaflets were ready to go out after July 5. But why wait six weeks after it has been sanctioned by the RB? Why let the Minister get the first word in when it was perfectly obvious that he would lose no opportunity of blaming us as and when it suited him?

In the same speech Dr. Dain explained that it was a considerable undertaking to circulate all doctors with these leaflets for them to hand on to their patients and he suggested that it might be done through Divisional public relations secretaries. It is not plain why these overburdened and unpaid people should be saddled with this when they need all their time to earn a living by doctoring, especially as there is an enormous and highly paid secretariat at Headquarters to do the job. Dr. Charles Hill and his assistants were quite capable of organizing a plebiscite with a haste for which the profession had no liking, yet when it comes to implementing the expressed wish of the RB in the simple matter of circulating some leaflets to doctors we meet with interminable delays and excuses. There seems to be a feeling at Headquarters that no matter what the RB passes or what the profession wants, it is for the secretariat to decide what shall be done with enthusiasm and dispatch and what shall be allowed to die through inertia—I am, etc.,

July 2 London NW1

R. HALE-WHITE

\* \* The Secretary of the BMA writes: "There are no excuses and there is no unnecessary delay. Headquarters, despite the many heavy burdens now falling on it, is doing its job 'with enthusiasm and dispatch'." 'Inertia' is hardly appropriate to a staff which is working 'all out'. No one who has not tackled this problem has any idea of the physical difficulties nowadays involved in the production of large quantities of leaflet and poster material. In a wide variety of ways, including the supply of background information to the Press, the Public Relations Department has acted on the SRM's resolution. Within two hours of the Minister's statement on July 2 the following rejoinder was issued to the Press:

It is difficult to understand Mr. Bevan. He announces with pride the numbers of doctors who are joining the Health Service. At the same time he cries to Heaven in indignation that doctors are not joining. Really, Mr. Bevan must not begin to blame the doctors for his troubles. As soon as the BMA decided to co-operate, doctors were advised they were free to join the Service. They could hardly be given that advice while the dispute was still on. The doctors didn't choose July 5 anyway. Why blame them if local executive councils are not ready with lists of doctors, which in any

case cannot be complete until after July 5? After all, it was Parliament which gave doctors until July 5 to decide."

The Chairman of Council has dealt with the point in a letter to *The Times* and in speeches, the Secretary has emphasized it in three public speeches.

In the past few weeks 600,000 copies of "The Private Patient" leaflet, which deals with one aspect of the sign-on muddle, have been dispatched from this office, mostly in small packets to individual doctors. At the moment it is going out at the rate of 10,000 copies a day.

The leaflet on "The New Health Service and You" was approved by the Public Relations Committee on June 17 and then sent to the printer. Printing and paper difficulties are great, and in fact many problems still remain. This leaflet will be issued direct to individual practitioners as soon as is humanly possible. 40,000 copies of a poster on the same theme for display in doctors' surgeries have been promised by the printer within a week or so. The leaflet is in the following terms:

#### THE NATIONAL HEALTH SERVICE AND YOU

July 5, 1948, was a notable occasion in our history. On that day the National Health Service started—the foundation of a comprehensive service for the entire community. The medical profession pledged itself at the start to do everything it could to make the Service a success. But—and there is a very big "but"—the Service cannot be a success unless the three parties concerned help to make it so. Doctors, nurses, and the other workers in the Service, the Government and the administrators, the public. All have a part to play. Each should try to appreciate the others' difficulties.

Remember, no fury wind was waded on July 5 to create new hospitals, new doctors, and new nurses overnight. Did you notice that to many of the benefits promised in the Government leaflet describing the Service a warning phrase was added—"as national resources allow"? This was added with good reason. It is vital that everyone should understand the facts and not expect miracles.

**The Family Doctor**—Under the new Service 28 million more persons suddenly became entitled to medical treatment without payment of fees. But there are no more doctors than there were before. Therefore, if there is a "run" on the surgeries just because the Service is "free at the time," doctors will be unable to give as much attention to each patient as they would wish. No one can give his best if he is overworked.

After the panel system started in 1911 the average number of times the average doctor had to see each patient suddenly rose from under twice a year to  $3\frac{1}{2}$  times a year, and that number has since risen to over 5 times. Even more heavy is the new burden falling on doctors now that the number of persons entitled to a free Service has shot up from 22 millions to 50 millions.

To carry out all the objects of the National Health Service Act and to provide reasonable conditions of work for doctors many more doctors are needed. To train a doctor takes at least five years. There can be no hope for a long time to come of providing all the doctors necessary.

**Health Centres**—The building of health centres, once described as the "keystone" of the new Service, has been postponed indefinitely because of the building situation.

**Hospitals and Specialists**—The hospitals are unable to cope with the demand on their services. On July 5, 61,000 beds were empty in the hospitals of Great Britain through lack of nurses and domestic staff. The country is short of 45,000 nurses, and there is no immediate prospect of finding them. Until this problem is solved there can be no substantial increase in hospital beds. Recently 33,000 patients were waiting for admission to the London hospitals alone. Many patients with tuberculosis have to wait a year or more before they can be admitted to a sanatorium.

There is an even more serious shortage of specialists in some branches. This again must make itself felt in the running of the hospitals at the start of the new Service.

**Appliances**—The free provision of spectacles, false teeth, hearing-aids, artificial limbs, and other appliances are benefits under the Act. But again, there is a shortage of all these things, and patients are waiting long periods for them. Inevitably this waiting time will greatly increase.

**How Everyone Can Help**—It is fair to the public that they should be told the truth about these and other deficiencies. The doctors will work their hardest to have them removed. So will every body else. But it will all take time. Do not expect too much too quickly.

Meanwhile, there are ways in which everyone can help his or her doctor to get round his work.

**Please**—Ask the doctor to call only if you can't get to his surgery and you really need him. Wherever possible, if you want the doctor to visit you, ask him before he starts his rounds. This helps him to plan his day, avoids needless journeys, and makes the best use of his time.

#### Public Relations

SIR,—The "Private Patient and the New National Health Service" pamphlet has been hailed as a fine piece of work, probably the best piece of work that has been done by the Public Relations Department. There have, however, been grumbles: (1) That the idea was too late, (2) that dispatch from B.M.A. House was too slow, (3) that distribution to individual members was too great a job for local public relations secretaries. Let us examine the facts before we jump to hasty conclusions.

1. Could the pamphlet have been issued to the public earlier? The answer is definitely no. We must not forget that until the S.R.M. at the end of May the profession was actively engaged in opposing service under the Act. How could we at one and the same time issue propaganda material (a) which in effect urged the public to boycott the Service and support the doctors in their fight, and (b) which stressed the advantages of remaining as private patients within the Service while continuing to draw all the other benefits?

2. Early in May specimen copies were issued to Divisional public relations secretaries, who were asked to state how many copies would be needed by the doctors in the Division if the profession decided to join the Service. Replies were slow in coming—in fact, some Divisions have only just sent in their first orders. However, 100,000 copies had been printed and the first bundles dispatched to doctors a few days before the S.R.M. The Ministry of National Insurance then issued fresh contribution figures which made the pamphlet inaccurate and it had to be revised, and having overcome paper shortage difficulties 450,000 copies of the revised pamphlet were obtained from the printers. Two members of the B.M.A. staff were detailed to do nothing else but bundle up and post them to Divisions. After two or three weeks, as orders were coming in very slowly from public relations secretaries, a copy was sent to each Division secretary, who was also asked to estimate the number needed and to order them. Yet what do we find? Some Representatives at the Annual Conference told me that they had not even heard of the pamphlet in their Divisions. If blame lies anywhere it is at Divisional level rather than at the Centre.

3. Surely Divisional distribution could have been from one or more centres, such as hospitals or nursing-homes or even doctors' houses? Stocks could have been left at each centre and the usual Divisional machinery could have been used to notify each member where to go to collect as many copies as he needed. This worked well in some areas and obviated a great deal of packing and posting for the Secretary. It also put some of the responsibility and initiative on the individual—surely not a bad thing in these days, when a few seem to be taking the burden of responsibility for the many—I am, etc.,

Bristol

WALTER WOOLLEY

#### A.R.M. Report Correction

SIR,—In the *Supplement* (July 3, p. 2) you print an account of the debate in the Representative Body on the motion by Dr. Breach (Bronley) asking for the formation of a committee to consider the conduct of the profession's case in 1948. You quote me as seconding the motion, and you go on to report verbatim the remarks of the Chairman of Council and of Dr. Gregg in which they "attack the mover and seconder" (to quote the Chairman's opening words) and wherein they indicated with considerable emphasis and heat their opinions that the reasons given by Dr. Breach and myself for the proposition were other than we stated. What you do not do is to publish my personal explanation given in the course of the debate that I did not second the motion but that the seconding was allocated to me by the Chairman of the Representative Body when he announced my name to speak, an error for which he subsequently apologized to the meeting.

As a result of a conversation with the Chairman of the Representative Body over the luncheon table I wrote a note to Dr. Hill stating that, as I had only seen the motion for the first time a few minutes before it was proposed and had specifically refused to second it when asked to do so, I must ask for my name to be withdrawn from the minutes as seconder. This was done, and I accordingly request you to print this letter as a correction and amplification of your account of the debate. In conclusion I would observe that, judging from your quotation in the leader of that issue of Mr. Churchill's saying, "The more one looks back the farther one can look forward," I appear to have been in good company in speaking in favour of such a principle—I am, etc.,

Harrow, Middlesex

J. B. WRATHALL ROWE

## SOME ASPECTS OF THE TREATMENT OF SKIN DISEASES

BY

JOHN T INGRAM MD FRCP

*Physician in Charge Skin Department General Infirmary at Leeds  
Lecturer on Diseases of the Skin University of Leeds*

All dermatological affairs assume an importance greater than appears on the surface because they are a reflection of the same problems as concern medicine as a whole. They are a little complicated by external influences, but the fundamental principles which apply to medicine apply to the skin and are there made manifest. So it is with the problems of treatment which more seriously test the ability of the physician as a healer of the sick than do most other departments of medical practice. It is an aspect of practice which each one of us should bring under review from time to time in a broad way and this is perhaps more than ever necessary when therapeutic advances proceed as rapidly as has been the case in the past few decades.

There are certain fundamental principles which have guided the wise physician through the ages. They have a basis in careful clinical observation and are built upon sound experience. They have stood the test of time and satisfy the simple demands of common sense, and should form the basis of all our treatment. To these principles are attached in fashionable abundance a number of therapies, sometimes empirical, sometimes founded upon interesting and valuable scientific discovery, and sometimes mere fads, but there is ever present the danger that these accretions may obscure the sound principles in the hurly-burly of medical practice.

### Some General Principles in Treatment

A first essential in treatment is to make an accurate diagnosis, to grasp the full significance of that diagnosis and often to convey that significance to the patient. Diagnosis is not covered by a tabulated series of labels and the attachment of a particular label to a particular manifestation. Treatment does not consist merely in the administration of a certain drug filed under the heading of such a label. Diagnosis and therefore treatment, rests almost entirely upon a careful history and a complete examination of the patient including his whole skin. Special tests necessitating elaborate technical facilities are of very secondary importance and need not concern us here. In a considerable proportion of cases effective treatment demands no more than the taking of a history and clinical examination except that it shall be shared and understood by the patient.

### The Organic Group of Skin Diseases

We find in dermatology that diseases fall broadly into two distinct groups. The first may be described by the old-fashioned term organic. These are structural changes with little disturbance of function and include congenital abnormalities, infective diseases and neoplasms. This constitutes the smaller group of dermatological ills seen by the doctor and for each disease in this group there is a more

or less specific line of treatment to be modified according to the characters and circumstances of the patient. In this field the physician may claim that it is he who treats the patient and that success depends almost entirely upon his knowledge and ability.

One or two examples may make my point clear. The diagnosis of erythema nodosum is not difficult. It is a reaction in a sensitized individual to organisms which have recently gained access to the blood stream from some focus of infection. Those are two very significant points. It is recognized that in this country more than 70% of those who suffer from erythema nodosum under the age of puberty do so by reason of a tuberculous infection. That then, is one major aspect of the problem, and if treatment goes no further than a careful overhaul for active tuberculous disease in the patient and in those around him it has been to some purpose. Warty tuberculosis of the skin results from external contact with the tubercle bacillus. But again, though it may do no more than point to the occupation of the patient, it may on the other hand mean that the patient himself or someone in his family or in a wider circle of contact is the subject of open pulmonary tuberculosis and is the source of the organism. If the lesion is on the buttock it is almost certain that the patient is himself infected in lung or bowel or ischio-rectal region.

Erysipeloid is a common infection of the hand in those who handle pork, fish, game, rabbits, etc., and is due to *B. rhusiopathiae suis*. It does not cause abscess formation, lymphangitis, or adenitis, and is responsive to penicillin therapy. To make an error of diagnosis and diagnose pyoderma or cellulitis and to incise may lead to sepsis and unfortunate sequelae.

So simple an affection as impetigo is not just a matter of a label and specific treatment. Its presence about the head and face often indicates an underlying pediculosis capitis or a focal infection such as a fissure or aural, nasal or dental sepsis. Furthermore, those in greasy or wet trades and those with greasy and wet skins are known to be particularly prone to sepsis, and treatment should be guided by these facts. Whatever the medication a first indication is to keep the parts dry and avoid greasy applications.

These illustrations in the field of organic disease demonstrate the importance of an accurate diagnosis and all that it means in effective treatment.

### The Functional Group

In the second group of dermatological ills comprising perhaps 70% of all skin diseases the stress is upon function, and structural changes play a minor part. In the first group we can almost imagine the disease pursuing its course independently of the patient. In the second group the disease is the patient is essentially individual, and merely expresses the functional response of that individual to the particular circumstances in which he finds himself.

\*Based on a lecture delivered at Staincliffe County Hospital, D. 14, on March 18, 1948.

e attach a number of labels to certain patterns of functional reaction which bear certain features, labels like eczema and urticaria, seborrhoeic dermatitis and psoriasis, but it is a grave error to imagine that the label is the disease and carries with it the implication of a definite course of treatment. To make a diagnosis here it is necessary to know something of the patient's background and inheritance, something of his health and temperament, his circumstances, his home and work, and to consider all those environmental influences which may bear upon and affect his reactions. To carry that diagnosis through to effective treatment it is necessary to convey to the patient an understanding of all these factors so as to enable him with appropriate assistance, to achieve an adjustment and stability in relation to his environment. It is indeed the patient who treats himself.

Infantile eczema is an illustration of this type of disorder. The child has a sensitive skin provoked to functional disturbance—itching—by external factors such as exposure, or by internal disturbances such as teething, which would not annoy the normal child. Protective and antipruritic applications such as tar paste are employed, and sedative measures are prescribed internally. But the problem is not quite so simple. There is not only a sensitive skin or even a sensitive ectoderm but a sensitive patient manifest in all his emotional and nervous reactions. This calls not only for great care and understanding in management immediately, but for consideration in relation to the training and rearing of the child and choice of school and career.

Such a child will generally be the offspring of a parent or parents of similar temperament, a likely aggravation for the patient and often responsible for an atmosphere of unrest and anxiety round the child. It may be necessary to remove the child, at least for a period, from the atmosphere during his early life. In any case success in treatment must be difficult if the parent cannot be brought to understand the nature of the disturbance.

Rosacea is another label that is entirely inadequate unless the significance of the reaction is appreciated by doctor and patient. A variant of blushing, it is clearly subject to emotional and endocrine imbalance such as occurs at puberty or the menopause. Not only the psychological but all those influences external and internal which can bear upon blushing and flushing must be brought under review, and the possibility of hypertension as another expression of vasomotor instability must not be overlooked, for, if present, it will be the major symptom. Fortunately this very embarrassing symptom, rosacea, is readily responsive to simple measures—small fractional doses of x rays with a mild sulphur and salicylic ointment locally and phenobarbitone internally. But success will be short-lived if the wider psychological and environmental aspects of each case are not dealt with and the patient given insight into them.

So it is with all affections in this large group of ills. The label of industrial dermatitis or psoriasis, of sycosis barbae, pruritus ani, or eczema is not sufficient to indicate treatment. The same treatment may upon occasion be applicable to all, for the cause of the disturbance may turn upon a question of domestic harmony, malnutrition, or endocrine dysfunction, or other endogenous influences of greater importance than the apparent external factor. All aspects of the problem must receive careful assessment in each case, for it is this integrity in diagnosis that is essential to treatment. This was often unconsciously appreciated by the wise physician of old, the good family practitioner. It is something which in the face of rapid scientific progress we are apt to lose, and it is something which cannot easily be reconciled with an ordered, scientific, and regimented medical service. At the same time its recognition in a big

way rather than on the individual plane constitutes one of the major advances in treatment through the development of psychological and social medicine.

#### An Important Point

A second point of major importance in treatment is to remember that the disease affects a human being and not a laboratory apparatus, that the disease has a natural history and tends to run a natural course of its own further, that its presence automatically sets in action a variety of defence mechanisms about some of which we may understand a little but about many of which we certainly know nothing. It is undoubtedly these defence mechanisms which ultimately effect a cure and we must be careful not to interfere with or harm their activities and must cut across them only with caution. In short, even with the most modern and scientific weapons it is still the patient and not the disease that must be treated.

In this regard it is pertinent to mention the value of rest, to stress the harm caused by interference, and to encourage a masterly inactivity. There is every inducement to practise the reverse. The patient urges us to do something, and to do something different. We are encouraged by a spate of medical literature not always based on a broad clinical experience. Such a wealth of medical preparations is placed at our disposal and so many are the diseases of uncertain aetiology that there is ever present the temptation to try one of the new drugs which seem to exercise magical powers. Sometimes the magic works, sometimes it does obvious harm, but how often it does unseen harm it is not possible to tell.

If dermatology reflects what happens in other spheres of medical practice—and I do not doubt that it does—this ability of the physician to create harmful disease should be stressed. The dermatologist constantly sees, and himself often produces, extensive dermatoses or disabling illnesses that have their origin in little or nothing and are literally created by an excess of treatment and misdirected zeal. We are ourselves in large part responsible for this—encouraging patient and worker to attack with treatment the most trivial of lesions, forgetful of or having lost faith in the healing powers of nature and particularly of the skin, and unmindful of the fact that this is the age of therapeutic danger. Antiseptics, sulphonamides, penicillin, and adhesive plasters readily convert a harmless abrasion into an area of eczematous dermatitis, and immediately a serious offence is created.

These problems are all too familiar. I may quote three cases. The first is that of an old lady of 84 who had never suffered from her skin in her life. Six months previously she was burnt by a poultice applied to relieve pain in her chest. This burn was treated with penicillin and sulphonamides locally. The resulting sulphonamide dermatitis was treated with tar, to which she was sensitive and now after six months she is distracted with a widespread eczema and intolerable itching.

The second case is that of a man of 48 who scratched his leg two months ago. This was treated with sulphonamides and penicillin in the ambulance room at his works, and now he must be admitted to hospital for at least six weeks to treat the dermatitis and oedema of the leg and the generalized spread resulting from treatment.

If nothing had been done in these cases it is probable that the patients would have recovered rapidly.

The third case, that of a middle-aged woman with a widespread dermatitis from the use of a liniment to relieve pain in a joint, is less unreasonable perhaps but we should always be alive to the harm that may result from interference.

The skin is slow to forgive eczema begets eczema and what is produced in a few days may take months or years to subside. The inherent sensitiveness of the skin, the powerful sensitizing properties of the metabolites which such reactions evoke, the effects upon the blood chemistry and upon the mind to mention only a few of the major influences which are set in motion are profound and we understand very little about them.

In dermatology and no doubt in other spheres it is of importance to be able to recognize the ill-effects of treatment is opposed to the evidences of the disease itself. I try to remember in practice to suspend all treatment in a case that is getting worse under seemingly rational treatment and especially in a case that is getting out of hand. It is always instructive to watch the effects of no treatment at all and one's measure of success should always be judged against that yardstick. It may be wise for the inactivity to take the form of some bland medicament and there are still many to be obtained, even though this is not as easy as in the days before the war for 'austerity' substitutes are apt to misqueride under the guise of old labels especially in relation to oils and fats.

Very many of the dermatological ills of which I have been speaking are themselves the expression of a patient's loss of confidence in himself. Whether or not that is the case it is very easy for the subject of a functional disorder of the skin as eczema or psoriasis to become anxious and feel insecure and doubtful of the future, more particularly if his disease seems to be a mystery to himself and his doctor.

Treat with confidence. It is probably true to-day as it has ever been in the past that the more able and experienced the physician the fewer and the simpler his therapies. With a full and careful diagnosis—and this rarely demands much technical assistance—and if the nature of the remedies prescribed is known the physician should treat his patient with complete confidence and not be disturbed from that course without serious consideration.

### Local Treatment

The question of the use of soap and water is always an intriguing one for the patient. Few skin affections are infectious or contagious, and so far as the attendant upon the patient is concerned the nurse or doctor ordinary soap and water toilet cleanliness is desirable and necessary, but nothing more. The lavish use of antiseptics is unwise, and the wearing of rubber gloves is an offence which may do much harm in the field of treatment confirming the patient in his feeling of being in outcast.

So far as the patient is concerned the use of soap and water must be guided by common sense. In some affections it is essential to wash thoroughly as in seborrhoeic disorders not associated with eczematous dermatitis. Seborrhoeic pityriasis and tinea vulgaris respond to washing and the addition of one of the modern soapless detergents to the washing water by cleaning the skin more thoroughly of its excess of grease will hasten the response. Expressions of skin sensitiveness like rosacea and eczematous dermatitis are aggravated by this procedure and it is often wise entirely to avoid washing the affected parts. It is of importance that the patient shall understand his ill and shall not approach it as a leprous offence of which he must be cleansed by vigorous scrubbing. The patient will often comment upon the injustice of his having skin trouble when he is so much more careful about his toilet than his neighbour. It is just that type of patient who is most likely to show a skin disorder by reason of his temperament but it is essential that his false approach to the problem should be corrected.

The same yardstick of common sense should be applied to the use of protective barrier creams before starting work in the factory or the home and to the use of cleansing agents after work. The suitable employment of such measures can be most beneficial but if employed without understanding and intelligence they may do great harm.

I want now to turn to some particular aspects of dermatological treatment. Local applications are rarely to be employed as therapeutic weapons, seldom is it desirable to attack. The purpose of local treatment is commonly to support and protect the skin to effect its own recovery, to improve the conditions under which it is functioning. For that reason the character and form of the application, its physical qualities, and the manner in which it is employed and applied are of more importance than the ingredients.

Local or general baths and lotions are valuable, especially for infected and eroded surfaces but they should be applied for only a limited period for fear of soddening and macerating the tissues. They should not be irritant as regards either temperature or ingredients; they should be isotonic and not unduly astringent. Normal saline is excellent for most purposes. As a mild astringent and antiseptic potassium permanganate 1 in 8,000 is valuable. Solutions of the dyes are bland antipruritic, antiseptic and astringent, but are not to be used to the point of producing scales or scabs which prevent the discharge of infected exudates.

Wet dressings are occasionally of value in soothing and reducing the acute oedema which may accompany sensitization reactions. Cold-water bandages are suitable, but should not be used for more than twenty-four to forty-eight hours.

Fomentations should not be left in place for four hours under oiled silk or they will macerate the skin, and if employed in the treatment of infections they will encourage spread. A session of three or four fomentations applied in the course of an hour once or twice a day, is the better routine. The starch and boric acid poultice is soothing and cleansing for sore and infected surfaces but a session of two or three replaced every three or four hours before they have set hard, is preferable to a twelve- or twenty-four-hour application followed by the tearing of the stiffened starch from the skin.

Calamine lotion is a useful application when properly employed. It should not be used as a wet dressing but should be applied to the skin like whitewash, with a brush and should be allowed to dry before bandaging. A thin stockinet sleeve (of the type used as padding in the orthopaedic departments) is an admirable dressing. If the lotion is applied with cotton-wool the powder which should be on the skin remains in the wool. The lotion must contain sufficient powder and I would suggest a prescription of the following proportions:

R/ Calamine	}	aa 40 gr (2.6 g)
Zinc oxide		
Glycerin		30 min (1.8 ml)
Aq. calcs		ad 1 oz (28.4 ml)
		Ft lot

If too astringent this may be alternated with or replaced by the following elegant liniment:

R/ Calamine	}	40 gr (2.6 g)
Lanolin		30 gr (2 g)
Ol. oliv		
Aq. calcs		aa ad 1 oz (28.4 ml)
		Ft lin

By far the most valuable local application however is Lassar's paste. Soothing and protective, it rests the skin, protects it from changes of temperature and from the

ing fingers of patient, nurse, and doctor and from inquisitive eyes. Containing as it does 50% bland powder it does not heat the skin or interfere with respiration or secretion, and it can—as can calamine lotion and liniment—carry a mild antipruritic such as 2% carbolic acid or tar or a mild mercurial antiseptic. The paste should be smeared on the skin so as to obscure the affected areas and should be covered with stockinet and left undisturbed, further paste being applied when necessary. The virtue lies in the physical character of this stiff paste, and it is important that it should be well dispensed, as is true of most applications used on the skin.

I have never subscribed to the view that doctors were efficient dispensers of dermatological preparations, and have some sympathy with the patient who complains that the hospital preparations are not the same as those which he obtains from his doctor.

A nurse or patient may destroy the value of a paste by heating it for greater ease of application. It should be applied patiently, gently, and evenly with the finger, and to the skin and not to a piece of lint.

The soft paraffin available at the moment is of an inferior quality and lower melting point. The pastes dispensed from this material are unsatisfactory, and the value of treatment is thereby impaired. Psoriasis, which will clear rapidly on Lassar's paste with dithranol 2 gr to the ounce (4 mg/g), may show no response to a paste dispensed with this paraffin. The addition of anhydrous lanolin has helped to correct the fault. Titanium dioxide is a bland powder with valuable properties, and can be usefully combined with soft paraffin and an emulsifying base to form a paste.

It is, I think, this important fact of the physical characters of the application rather than the ingredients which accounts for disappointment over the introduction of emulsified bases. These have not, in my experience, made much difference to the local treatment of skin diseases. In theory they are more penetrating and carry the medicaments into more intimate contact with the skin, but, as I have suggested, this is not nearly so important as the protection and support afforded by the preparation, and in this regard soft paraffin remains an invaluable base. The great value of the emulsified base often incorporated in ointments and pastes is that it facilitates their removal, and this is appreciated in treating the scalp.

I would suggest, however, that a practitioner should rarely go beyond the range of those simple and tried remedies which I have enumerated. I would particularly deprecate the use of the anaesthetic ointments and applications now on the market. They readily provoke a sensitization dermatitis which may become widespread and distressing and may leave the skin in a highly sensitive state for a long period.

There is a general feeling that a great increase has occurred in the number of cases of sensitization dermatitis, and not only to these recognized sensitizing agents. I believe this is true, and that eczematous dermatitis is often much more intractable than it was before the war. It has been suggested that diet may play a part in this, and it is possible though my temperament would incline me to regard emotional and nervous frustration over the past decade as a more potent influence. I would not, however, dismiss the part which may be played by the increasing introduction of sensitizing drugs into topical applications—anaesthetic drugs, sulphonamides, and penicillin being placed high on the list. I have already referred to the intractable character of epidermal sensitization once it is set in motion, and this is an added reason for the limitation of local therapy to simple measures.

### Sulphonamides and Penicillin

When sulphonamides or penicillin are considered necessary it is preferable that they should be given by mouth or parenterally, for sensitization by this route, though it may not be helpful, is not such an intractable problem as epidermal sensitization.

Though these drugs have saved lives and proved their value in surgery and in war, that does not justify their promiscuous and irrational use in other spheres and the ready production of disabling dermatoses.

In dermatology it is almost always desirable to employ sulphonamides by mouth and not locally. I believe that the period over which the drug is given should bear some relation to the natural course of the disease. I believe also that dosage should be reasonable and not massive or toxic and should not be such as to embarrass the natural defence mechanisms of the body, and particularly of the skin, but should assist that natural defence. It is apt to be forgotten that there is a patient when these relatively simple skin infections are attacked, and with minds charged with chemotherapy, we too often disregard other important factors in the case which relate to the soil which has fallen victim to the infection.

I should qualify this and state that I believe that in certain sites and under certain conditions pathogenic organisms may thrive on a skin or mucous membrane surface without infecting that surface, and a topical application may then serve a useful purpose.

Penicillin has a very small place in ordinary dermatological practice. As a local application, and particularly as a cream or ointment, it is a menace, and penicillin dermatitis has become a common diagnosis in the out-patient department and is a very troublesome affection. It would seem rarely to be necessary to employ the drug for the majority of surface skin infections where there are other effective remedies, and its use in eczematous affections, whether infected or not, carries a high risk of serious aggravation. There would seem to be some clinical evidence that in the parenteral treatment of deeper infections like boils and carbuncles the drug may cut across the natural defence mechanisms and leave the patient, after the cure of the initial lesion more vulnerable than he was previously.

In this field let me again stress the undesirability of unnecessary interference. Pustules, boils, and carbuncles are better left alone. Squeezing and surgical interference aggravate. Dry heat, short-wave therapy, and x-rays are better local measures.

### X-ray Therapy

I cannot leave the field of local therapy without a word about x-rays. When used in small fractional dosage, unfiltered and at low voltage (indeed, as Grenz rays if available), they are invaluable in the treatment of all disorders of function in the skin. Dosage and the spacing of treatments must be accurate. The treatment must form part of a scheme of general treatment, for it is only local therapy and is wasted if not supported by general measures. For fear of inadvertent overdosage great care should be taken to ascertain whether the patient has previously received superficial x-ray therapy.

Every patient undergoing x-ray therapy should receive a card recording the dosage given and should be warned to present that card whenever further x-ray treatment is under consideration. This is particularly necessary when giving more than a fractional dose, as in the treatment of ring worm of scalp, keloid, and benign or malignant tumours. Grenz rays are relatively safe, and it is to be hoped that

the full sun be made available and will be more widely employed in place of rays.

Thorium X has not in my hands been of much value. It will fade but not clear a port-wine stain though it is the only measure that may be effective in that rare dermatosis, naevus verrucosus. Theoretically thorium X as a source of light particles should be a useful and safe measure in the treatment of superficial affections but it has proved disappointing.

### General Treatment

My previous remarks indicate the stress I would place upon the general approach to and investigation and understanding of the dermatological problem as a part of treatment. I would equally stress the importance of general as against local treatment and general treatment may include the administration of drugs.

I have time for only a word or two upon a few of the drugs more recently introduced most of them dangerous drugs about which we still have much to learn. They should be used with caution and only where the character, gravity or intractability of the affection justifies it, and patients so treated should be kept under close clinical observation.

I have mentioned the sulphonamides which can help considerably in the control of pyogenic affections and in some other ills such as dermatitis herpetiformis, where the effect would appear to be along some other channel than the combating of infection.

Penicillin is of limited value in dermatology, but will sometimes clear or relieve cases of chronic or recurrent eczema or chronic lymphangitis and elephantiasis. One of the distressing effects of penicillin therapy—viz., pruritus and urticaria—may be controlled by another type of drug the antihistamines. These again are of more interest from the laboratory and experimental point of view than the clinical but they may be helpful in cases of allergic reaction of known cause and limited course. We cannot feel entirely happy however in introducing agents into the system which counteract so essential a metabolite as histamine.

I must say a word about the use of calciferol in massive dosage as employed in the treatment of lupus vulgaris. As a vitamin it may be regarded as harmless but in this dosage it is dangerous and should not be employed over any long period in the treatment of trivial affections. The effects in lupus vulgaris and in sarcoidosis may be quite remarkable but a careful watch has to be kept upon the blood chemistry and particularly upon renal function.

The general treatment of disorders of function calls for a careful assessment of the patient as a whole and his adjustment to life and his environment. That assessment must be appreciated and understood by the patient if treatment is to achieve success. I have already referred to this.

Symptomatic treatment will often assist and encourage the patient in his efforts but it must be sustained and be employed as a help and not as a direct or specific therapy to be prescribed for a limited period. In ideal circumstances the patient employs such symptomatic remedies as the doctor suggests in the light of his understanding of his problem and of the purpose of those remedies. Again it is important that the patient shall find benefit from and not be disturbed by such measures. They may serve as a supplement to the diet, a substitute for a holiday, an antidote to overwork, worry or fatigue or even to counter the stress of an insupportable climate. They are not of themselves cures for a disease but rather comforts for the patient and should be recognized as such and should be employed in a very individual manner and with proper discretion.

## GLOBIN INSULIN: A CLINICAL STUDY

BY

G. M. WAUCHOPE, MD, BSc, FRCP

Honorary Consulting Physician, Royal Sussex County Hospital, Brighton; Honorary Physician, New Sussex Hospital, Brighton

Globin insulin (GI) was introduced in 1943 as a slow acting insulin intermediate in duration of action between protamine-zinc insulin (PZI) and soluble insulin (SI). It is in many respects similar in action to Hagedorn's original protamine or delay insulin. It has been slow to gain recognition in this country, but from the patient's point of view offers the obvious advantage of simplicity and now that the management of diabetes has become the incultation of a *modus vivendi* rather than a *regimen vivendum* it is important to eliminate time-consuming or fussy procedures so far as is possible.

### Material

This survey is based on the records of 366 ambulant patients under regular observation who have been taking globin insulin for one to four years. They are drawn from the diabetic clinics of the Royal Sussex County Hospital and the New Sussex Hospital, Brighton, and from private practice. At the present time 68% of those attending one clinic and 66% of those attending the other are on globin insulin. The majority of the patients already attending the clinics were balanced on a combination of PZI and SI given before breakfast. It was recognized that in order to obtain the expected action of SI it must not be mixed in the syringe with PZI (Wauchope 1940, Peck 1943) and most of the patients had been taught either to inject one kind of insulin immediately after the other through the same needle or to give two injections. When patients mixed the two kinds of insulin in the syringe the dose of SI was equal to or greater than that of PZI and was difficult to assess owing to variations in the amount of mixing (Wauchope, 1940). A few patients were satisfactorily balanced on one dose of PZI, and a few older people of regular habits remained satisfied with two doses of SI a day.

At the time globin insulin was introduced the war was in its fourth year, air raids were frequent and almost all the diabetes attending the clinics were in full work in factories, civil employment, household duties etc. Many were air-raid wardens in addition. Their hours were irregular, their sleep interrupted, and the insulin had often to be given in poor light. In these circumstances from late 1943 onwards new patients were started on a single dose of globin insulin usually before breakfast; they were balanced as out-patients unless their illness was first recognized by the onset of coma.

The diet utilized the protein and fat allowed by the Ministry of Food which together with the bicora and egg-rations supplied about 1400 calories. C 120, P 28.0, F 103.5 (C 30 g, P 70 g, F 115 g). The rest of the calories required were made up mainly of carbohydrate and such protein as was available. A start was made with 200 g of carbohydrate which was added according to the needs of the patient. In practice very few eat the whole of the fat ration and many have at least one meal a day at a canteen or restaurant.

The results were unexpectedly successful and gradually GI became the insulin of choice. Many patients who had been on PZI and SI and who for one reason or another needed readjustment were changed to GI.

The times of the clinics allow for a routine blood-sugar estimation about four hours after insulin and breakfast; the patients test their own morning and evening specimens of urine and bring a chart or notebook for inspection.

The criteria for a satisfactory balance are (1) the comfort and well-being of the patient, (2) the attainment and maintenance of a reasonable weight, (3) absence of thirst or polyuria at any time during the 24 hours, (4) absence of ketosis, (5) absence of insulin reactions, (6) a normal blood sugar before the midday meal, and (7) small amounts of sugar in the morning and evening specimens (green reaction to Benedict's solution). Points 1 to 4 have been almost universally maintained in the absence of complications, points 5 to 7 naturally vary from time to time.

### Age

The patients may be considered under three categories according to the age at which they came under observation: (1) the young, who range from 2½ to 20, (2) the active working population, from 21 to 64, and (3) the old, from 65 onwards. The numbers of patients in each category and the dosage of insulin are set out in Table I.

*The Young (under 20)*—It was expected that these would do well on G I. Hagedorn's delay insulin had often been found useful for those whose last meal was at 5 or 6 p.m. and who were therefore prone to insulin reactions at night on P Z I.

TABLE I

Age	Dosage of Globin Insulin in Units						Total No of Cases	Under 40 Units	Over 40 Units
	0-20	21-40	41-60	61-80	81-100	100+			
Under 20	3	7	11	4	2	0	27	37%	63%
Active workers 21-64	90	84	52	10	0	2	238	73%	27%
Retired persons over 65	52	32	9	5	0	3	101	83%	17%
Total	145	123	72	19	2	5	366	73%	27%

The buffer substance of which 1 ml was put into each bottle of delay insulin, had occasioned difficulties, first because the amount was not always accurately measured and there was not enough for the last bottle of insulin, and secondly because each issue of insulin had to be in multiples of six bottles, which did not accord with the times of the visits. Moreover soluble insulin had often been combined with the delay insulin so that two kinds were used. Globin insulin given alone was therefore a great advance in simplicity, and was welcomed by the mothers and by the children and young people themselves.

*Active Workers (21-64)*—The great majority (65%) are in this group, their occupations do not differ from those of the non-diabetic population and include professions and trades, indoor and outdoor employment, clerks and farm labourers. There is even one serving soldier. Most of those who worked in factories during the war are now in other employment not involving night shifts. Many of the women are housewives responsible for families; there are school teachers, nursing sisters, nurses in training, typists, shop assistants and domestic servants. Their lives are not without incident, but they have been remarkably free from severe reactions.

*Retired Persons (over 65)*—Many are of the stable type of diabetic who would do well on any kind of insulin. Some are too fat but most are normal in health and weight. As would be expected the majority (83%) are on small or moderate doses (under 40 units).

### Dosage

It will be observed from Table I that the majority of patients of all ages (73%) are taking less than 40 units of insulin, this is, of course, not peculiar to globin insulin.

It has been suggested (Malins, 1945) that globin insulin has a limited use for patients on small or moderate doses, it is pertinent, therefore, to consider those on the larger doses. In this series the only category in which the majority are taking over 40 units is that of the young people, the dosage is, however, not high, only two patients taking over 80 units (88 in each case).

One is an overgrown thin lad now 18 who came under observation in 1941 at the age of 10. He was difficult to

balance, having a low renal threshold, and for five years was first on P Z I and S I and latterly on a combination of P Z I delay insulin, and S I (total dosage 88 units) in an attempt to avoid reactions. He began G I in January 1946, and has been much steadier on 80 to 88 units, he has left school and is working as a newsagent.

The other patient is the daughter of a farm labourer in a remote country district where supervision and a satisfactory diet have been impossible, she came under observation in 1942 at the age of 10 and during the next two years was often admitted to hospital for rebalancing after insulin reactions or ketosis. She has been on globin insulin since January, 1944 and has had no reactions beyond an occasional shakiness before meals. She has just left school at 16 and is working as a daily domestic.

The largest individual doses in this survey are taken by patients in the category of active workers—two women on 156 and 176 units.

One is an example of the case whose needs rise steadily. She is an energetic housewife now aged 53, and has had no illness or reactions. The only complication is benign vascular hypertension. From 1936 to the end of 1941 she was on two doses of S I, the total was raised from 48 to 100 units to balance blood-sugar readings of over 300 mg per 100 ml. From January, 1942, to August, 1944 she was on P Z I and S I, which was raised from 96 to 120 units, the blood sugar being again over 300 mg per 100 ml on many occasions. From September, 1945, till the present time she has been on G I starting with 120 units she reached a maximum of 180 units in 1946 and is now on 156 units. The blood-sugar estimations have been more reasonable 218 mg per 100 ml being the maximum in 1947, with a minimum of 87 mg. Her weight 9 st 6 lb (59.9 kg) in 1936 is now 10 st (63.5 kg).

The other is a stout hard-working ward maid now taking 176 units. Her blood sugar is usually in the region of 175 mg and her needs have been high from the outset in 1946. She began with 80 units of G I and was raised fairly quickly to 170 to 180 units on which she has remained steady.

Of the old people 83% are taking less than 40 units, but it is surprising to find three women on doses of over 100 units.

The first is a thin old person of 78 who has been on 120 units for the last two years and who comes to the clinic from a neighbouring town 10 miles away. The second, on 156 units, is now 64. She has had diabetes for over 20 years and came under observation 16 months ago with thirst, loss of weight, and lassitude. She was on 60 units of S I in the morning only, and her blood sugar four hours afterwards was 300 mg per 100 ml. She was balanced on G I and has taken 112 to 120 units since September 1947 with excellent control. The third, a woman of 65, was an in-patient at the National Hospital for Nervous Diseases for the investigation of a cerebral lesion when glycosuria was discovered in 1946. She returned home and her diabetes was balanced on 100 units of G I. She has been fairly stable on 104 to 108 units since early in 1947.

The patients on the larger doses of globin insulin do as well as those on moderate or small doses. There is no clinical difference, and none in this series are of the unstable type of case. They are not subject to reactions, and apart from the third case, just mentioned, have no complications. It will be seen that in Case 13 (Table II) 124 units of G I gave a steady level throughout the day, the patient was sent home on 128 units.

### Insulin Reactions

Among 150 patients whose notes are well documented over several years, 40 (27%) reported reactions and 110 did not. Most of those who reported any reactions have had many during the years of observation. Eleven who were formerly on a different insulin have had reactions on both in two cases they were severe on P Z I and S I but slight on G I. In addition six reported reactions on other insulins.

and none on G I. Of the whole number of reactions reported, only three were severe. These cases were (1) a corporation labourer who mistook the strength of insulin supplied injected a double dose, and was brought to hospital in coma, (2) a man driving a car who omitted his mid-morning lunch, was summoned and deprived of his driving licence, (3) a woman on G I since 1944, reported being taken home incapable in a police car at tea-time. She has always been subject to reactions, and when on P Z I and S I had many severe attacks, in one of which she was admitted to hospital in coma.

The incidence of reactions is not related to the age of the patient nor to the dosage of insulin, the young people have had few and the old have not been free. The third patient just mentioned, who had more reactions than any in the series, is a married woman of 53 taking about 40 units—one would suppose a moderate case. It is generally difficult to relate the reactions to the carelessness of the patient.

*The Time of Reactions*—The times of 126 reactions on globin insulin taken before breakfast, as reported by the patients, are: midnight to 7 a.m., 12, 10.30 a.m. to 1 p.m., 75, 3 to 6 p.m., 30, 7 to 10 p.m., 9. It is perhaps surprising, in view of the reputed slow action of globin insulin, to find that by far the greatest number of reactions occurred from 2½ to 5 hours after taking it. A mid-morning lunch is as necessary with G I as with P Z I and S I. The next common time is in the afternoon about tea-time, so that it is a mistake to omit or be late for tea. A few reactions have occurred between midnight and breakfast but in most cases it is unnecessary to take a late buffer meal. The fewest reactions were reported in the late evening before and after supper, and this is the time of day when the blood sugar is usually at its highest.

Patients appear to dread nocturnal reactions though to an observer it would seem to be a safer and more convenient time than when out and about. Many have spoken of the relief from this dread afforded by globin insulin. Local reactions have been inconspicuous and mainly due to error in the technique of injection, a few patients complain of more stinging than with other kinds of insulin.

### Examples of Satisfactory Control

It is difficult to demonstrate by figures the success or otherwise of insulin control. A few clinical examples of satisfactory balance are given.

*The Ordinary Case*—A cowman aged 45 came under observation in 1944. His symptoms had been present for one month. He was tall and thin and weighed 11 st 7 lb (73 kg). No physical signs of disease were found. A radiograph of the chest revealed fine fibrosis at the base of the left lung but no evidence of pulmonary tuberculosis. There was moderate hypochromic anaemia. His blood sugar was 240 mg per 100 ml and there was heavy glycosuria with traces of ketones in the urine. He lives in a village 18 miles away from the hospital and continued at work. He was balanced in a few weeks and has remained on G I 54 to 56 units since November 1945. He has had no reactions and the range of blood-sugar estimations has been from 100 to 150 mg per 100 ml. He now weighs 12 st 6 lb (78.9 kg). His work is extremely hard, he rises in the dark in winter to milk and works till sunset in the harvest. His appetite is enormous, and he eats mountains of bread and potatoes.

*The Man Working on Shifts*—A police constable aged 35 came under observation in November 1944. His symptoms were of 10 days duration: thirst, polyuria, loss of weight, lassitude, inability to run upstairs. He was 6 ft 2 in (1.85 m) in height and weighed 10 st (65 kg). No physical signs of disease were found. There was heavy glycosuria but no ketosis although the blood sugar was 660 mg per 100 ml. He was off work for three weeks, and was balanced as an out-

patient on G I 54 units. Since January, 1945 his insulin needs have varied between G I 50 and 56 units. The blood sugar taken at intervals of one to two months, has been twice above normal limits—250 and 220 mg—and has otherwise varied between 115 and 180 mg. He has had no reactions, his weight is now 11 st 9 lb (73.9 kg). His only sick leave was on account of a Colles's fracture sustained in the course of his duties. His shifts vary from week to week: (a) 6 a.m. to 2 p.m., (b) 2 to 10 p.m., (c) 10 p.m. to 6 a.m. the time of taking insulin is varied accordingly.

*Various Types of Insulin*—A girl who came under observation in 1927 at the age of 19 was balanced in hospital on S I three times a day. She remained on this system from December 1927 to December, 1939. The diet was 2,000 calories with about 60 g of carbohydrate. Her weight increased from 8 st 8 lb to 11 st (54.4 to 69.8 kg). There was persistent glycosuria and her blood sugar varied from 275 to 480 mg per 100 ml except for an isolated occasion when it was 150 mg. She was admitted in pre-coma in 1928 and 1932 and appendicectomy for acute purulent appendicitis was performed in 1932. In 1936 radium was applied for menorrhagia and after this she began to have bad insulin reactions on S I 70–80 units a day in three doses. Blood sugar estimations of from 77 to 350 mg were recorded during the years 1936 to 1939 inclusive. In December, 1939 a mixture of P Z I and S I was given in the morning with at first S I in the evening the total dosage varying from 75 to 38 units. The carbohydrate of the diet was increased to 150 g. She continued to have many reactions, the blood sugar ranged from 71 to 283 mg per 100 ml and she was admitted in insulin coma in 1941. In 1942 and 1943 she was rather more steady. In 1944 she underwent hysterectomy for menorrhagia due to fibroids. After this she began globin insulin and apart from one admission in diabetic pre-coma owing to an intercurrent illness has been much steadier and has reduced the dose from 72 units to 34. She has had no reactions, is taking 250 g of carbohydrate, weighs 10 st 6 lb (66.2 kg), and is in full work as a housekeeper.

This remarkable case which has been in the hands of many physicians and surgeons is noteworthy for four reasons. First, the long duration; secondly, the persistence of hyperglycaemia during the first 12 years of the patient's diabetic career; thirdly, the successful weathering of two major operations; and, finally, the present well-being, reduction of insulin needs and hard-working capacity at the age of 40.

*A Child*—John D. came under observation in 1942 at the age of 5. He was balanced as an in-patient on 14 units of delay and 14 units of soluble insulin. His weight was 3 st 3 lb (19.3 kg). He went to school and was inclined to have reactions on the way home so that the soluble insulin was gradually eliminated but it was again found necessary in 1943. At the end of 1943 his weight was 3 st 7 lb (22.2 kg) he was on D I 20 and S I 10 units and his blood sugar had varied during 1943 from 268 to 507 mg per 100 ml while reactions at tea time were reported. In January 1944, he began globin insulin and has continued satisfactorily. He is now 11 is 4 ft 7 in (1.4 m) in height, and weighs 5 st 2½ lb (32.8 kg). He has had no reactions for a year. This case illustrates the difficulties of insulin treatment of a child in a large family and the relief afforded by a simple procedure. He is the sixth in a family of seven, his father is a working man who gives the insulin (G I 40 units, 80 units to the ml) at 7.15 a.m. before he goes to work. His mother prepares breakfast for the father, two youths at work and five children for school. It may be supposed that John's diet is free: he has dinner at school and comes home to tea at 5 p.m.

### Control Throughout the Day

In order to obtain a view of the control during the day the records of patients who have been in hospital for some complication and whose blood sugar has been estimated before leaving are shown in Table II. It will be seen that in most cases the blood sugar rises in the evening, falls during the night, and is lowest before midday dinner: this is consistent with the experience of out-patients in the times

TABLE II

Case No.	Age	Globin Insulin in Units	Blood Sugar in Mg per 100 ml			
			6 a.m.	Noon	6 p.m.	10 p.m.
1	37	32	175	125	200	
2	30	60	116	—	131	
3	7	38	75	256	118	
4	16	120	112	85	225	
5	65	16	162	—	150	
6	57	60	156	131	93	
7	51	16	150	—	193	
8	50	32	137	143	100	
9	70	40	106	112	243	
10	70	20	106	187	87	
11	55	12	100	131	181	
12	61	42	168	212	137	
13	68	124	181	231	187	
14	63	32	62	93	181	
15	12	28	112	112	125	
16	42	24	106	225	106	
17	19	36	193	100	200	
18	36	32	131	234	156	
19	64	12	112	162	212	
20	21	68	112	140	131	
21	21	68	474	137	200	394

of their reactions. The control was reasonably good, though in some of the cases a readjustment of the dosage or the times of the meals was made before the patient left hospital—e.g., cases 3, 13, 14.

#### Failures

In a few cases there is an escape of control in the late evening, sometimes lasting all night and causing nocturnal polyuria. Often a redistribution of the times and amount of food rectified it, or a temporary evening dose of 8–12 units of soluble insulin while the globin is being adjusted is indicated, this can be left off gradually after a week or two. Case 21 (Table II) shows this escape—Case 20 is the same patient after readjustment.

In those few cases in which the blood sugar is low at noon and the evening dose remains necessary a transfer to PZI alone may solve the difficulty. This has been successful in the cases of two boys.

#### Discussion and Conclusions

It has been questioned whether, since PZI and SI in various combinations give good results, there is need for a third type of insulin. Rabinowitch *et al* (1947) discuss this, and after careful studies of ambulant patients on PZI or GI alone, PZI and SI in separate syringes, or SI twice a day found that the fasting blood sugar was lower with PZI alone than with GI alone, but the postprandial level was lower with GI. They obtained the best control with GI in the morning and PZI in the evening. Roberts and Yater (1947) in a survey of 97 cases recorded a better control with GI than with PZI in 70. Malins (1945), in a clinical study of 36 cases, considered that globin insulin has a limited place in the treatment of mild and moderately severe cases.

My impression has been—and a survey of the notes confirms it—that all types of patient do as well on a single dose of globin insulin each day as on other kinds of insulin, singly or in combination. From the doctor's point of view it is easier to adjust the dose than with the varying combinations of PZI and SI even when they are given separately, when they are mixed in the syringe a stable balance is always difficult.

The speed and efficiency of the clinic is increased. The opportunities for mistakes and confusion in measuring the dose are greatly lessened, as is the time consumed in teaching the patient self-administration. PZI given alone has the same advantages, but, owing to the longer time which elapses before it begins to act and the prolonged duration of the action, is of limited application.

Nearly all patients who have transferred from another type of insulin to GI prefer it on account of its simplicity

Many who, for one reason or another—e.g., being admitted to other hospitals—have been rebalanced on PZI and SI have asked to return to GI. They say that they feel safer from reactions and that it is much easier and quicker to take.

Globin insulin is, I believe, likely to become the insulin of choice in ambulant uncomplicated cases. It achieves the maximum degree of simplicity so far attainable—one dose of one kind of insulin once a day. Soluble insulin remains the type for use in all emergencies.

#### Summary

The notes of 366 diabetic cases treated as outpatients with globin insulin are reviewed, the dosage of insulin in different age groups and the incidence and times of reactions are recorded, and an attempt is made to assess the degree of control obtained.

The opinion is put forward that globin insulin alone is the best type of insulin available at present for uncomplicated ambulant cases of diabetes.

It is a pleasure to thank Dr. Prowse and the other physicians and surgeons of the Royal Sussex County Hospital and those of the New Sussex Hospital, for the use of notes of cases seen by them before they came under my care.

## RENAL COMPLICATIONS IN DIABETES MELLITUS

WITH SPECIAL REFERENCE TO THE KIMMELSTIEL-WILSON LESION

B3

A. LYALL, MD, FRCP

Lecturer in Clinical Chemistry, University of Aberdeen

In the prolonged observation of patients under treatment for diabetes mellitus one of us has been impressed with the relatively frequent occurrence of albuminuria. In a number of these cases clinical and laboratory evidence of progressive renal failure was observed, and the condition was often complicated by retinal changes and hypertension. These changes were earlier interpreted as evidence of progressive vascular degeneration in most instances, but the observation made by Kimmelstiel and Wilson in 1936—that a pathological change in the glomeruli of the kidney seemed to be a typical finding in diabetes—suggested a review of this problem.

Kimmelstiel and Wilson (1936) observed hyalineization of intercapillary connective tissue in the kidney in eight patients, all of whom except one had suffered from diabetes and in whom terminally, oedema and renal failure had occurred. They named this condition intercapillary glomerulosclerosis. Following on this observation several workers contributed further examples from both the pathological and the clinical aspect. Anson (1938) found six diabetic cases with similar lesions. Derow, Altshule, and Schlesinger (1939) reported a further example, and in the same year Newburger and

Peters (1939) published a review of nine cases, with post-mortem evidence in four. Herbut (1941), in a review of 2 000 consecutive necropsies at the Jefferson Hospital, Philadelphia, found a further nine cases fulfilling all the requirements previously described. Porter and Walker (1941) published the results of an analysis of the clinical and laboratory features of eight cases, with post-mortem verification in six of them. Siegal and Allen (1941) found the characteristic glomerular lesion in 35 out of 105 diabetics, and Horn and Smctana (1942) recorded the finding of 33 cases out of a total of 144 diabetics. Since then there have been publications on this subject by Mauser, Powe, and Michael (1942), Laipply, Eitzen, and Dutra (1944), and Bell (1946). The last-named devotes an entire chapter of his monograph to it.

In spite of these contributions there seems to be as yet no general recognition of this complication in the diabetic life and so far as we are aware no review of this subject has appeared in the British literature. This may not be surprising, since most of the work appeared in America during the war years.

### Presentation of Cases

The material analysed in this paper consists of data collected from 24 patients suffering from diabetes mellitus in whom progressive renal complications have been observed and in seven instances followed to necropsy. In the majority

the clinical manifestations were diabetes for a longer or shorter period followed by hypertension, arteriosclerosis, retinopathy, albuminuria, and chronic uraemia, although not always definitely in that order.

The cases, presented in the accompanying Table, are provisionally divided into groups, although in a few instances overlapping may occur: (1) twelve patients showing the onset of hypertension and renal failure after a prolonged diabetic state; (2) three patients who developed symptoms and signs of subacute nephritis during the course of diabetes; (3) six patients who at the time of their initial complaints were found to have coincident diabetes, arteriosclerosis, retinopathy, and renal damage; (4) three patients with diabetes and intercurrent urinary infections resulting in renal failure.

### Group 1

All the patients in this group with one exception were over 50 years of age, and all with one exception had a long history of diabetes, having been observed over the course of the disease by one of us. The average duration was 10 years. The degree of diabetes was moderately severe in all but two cases. The incidence of diabetic coma as an episode was low in this group. In Case 2 the onset of the disease was with severe diabetic acidosis and in Case 3 diabetic coma had occurred once. Incidents of sepsis occurred occasionally, but only in Case 2 could these be classed as numerous.

Hypertension was of the more severe degrees in all except three instances, and only in two was the diastolic pressure below 100 mm Hg. In seven instances hypertension appeared relatively late in the disease, from five to ten years after the onset of diabetes. Retinal changes usually appeared at periods of one to two years after hypertension was observed. Albuminuria was noted quite early in the disease in several instances, being sometimes transient but usually present when hypertension was established. Evidence of failing kidney function could nearly always be found by urea-concentration or urea-clearance tests in the earlier stages. Moderate increases in blood urea were usually present for about three years. The later stages of renal failure were nearly always accompanied by hypochromic anaemia of mild degree. Oedema, at first of the feet, occurred early in the onset of renal failure and was usually accompanied by hypoproteinaemia where this was investigated. In most cases generalized oedema occurred and in three cases was severe, being accompanied by ascites and pleural effusions. Detailed descriptions of Cases 1, and 5 illustrate the course and mode of termination of this group.

### Case 1

This patient was first seen in 1926 complaining of loss of weight, thirst, polyuria, and pruritus of a few months' duration. The urine contained sugar but no acetone or albumin. Both eyes showed central conical nebulae, but peripheral fields were full and no fundal changes were present. A sugar-tolerance test showed moderately severe diabetes with blood sugar values of 0.202, 0.256, 0.271, 0.306, 0.271%. The patient was treated by diet alone and continued in fair health for the next five years. In 1931 she was admitted to hospital complaining of pain in the left renal angle. There was a moderate degree of cardiac enlargement and the blood pressure was 172/94. No evidence of a renal calculus was found. Treatment with insulin (15+15 units) was started and the blood sugar was kept within the limits of 0.142 to 0.177%. Examination of the eyes showed a few retinal haemorrhages.

From 1931 to 1934 the patient attended the diabetic clinic regularly. Her weight increased from 138 to 142 lb (62.6 to 64.4 kg) during this period. The blood sugar remained within the limits of 0.139 and 0.201%. The Wassermann reaction was negative and a test meal showed achlorhydria. No albumin was found in the urine during this time. The blood pressure increased to 185/100. Vision showed gradual degeneration from lens opacities, vitreous opacities, retinal haemorrhages, and exudates. The blood urea was 21 mg per 100 ml.

In 1935 and 1936 the blood sugar was less easily controlled, the value increasing to 0.279%. The blood pressure rose to 190/100 and the blood urea increased to 44 mg per 100 ml. During 1937 to 1939 the patient began to lose weight and to

under good control' (in the region of 0.1%), but the blood urea had increased to 63 mg per 100 ml. In 1943 the patient was admitted to hospital, weak, tired, drowsy, and with sickness, vomiting and oedema. The blood sugar was normal and the blood urea 75 mg per 100 ml. The urine showed much albumin and numerous hyaline and granular casts. She lapsed into coma.

FIG 2—Case 1 Composite photomicrograph  $\times 140$  H and E

FIG 3—Case 1 Photomicrograph  $\times 260$  H and E

FIG 1—Showing progress of disease in Case 1

have transient oedema of the ankles. In 1940 her weight fell to 110 lb (49.9 kg), there was oedema of both ankles, sepsis of the right great toe, and albuminuria, with pus cells and granular casts in the urinary deposit. The blood sugar was kept

of the uraemic type and died. Graphically the course of the disease is presented in Fig 1.

At necropsy oedema of subcutaneous tissue, pleural effusion, and gelatinous oedema of the meninges were found. The kidneys were enlarged, firm, and tense under the capsule. The naked-eye appearance was of chronic nephritis or nephrosclerosis with subacute glomerulonephritis superimposed. Dr Jane Davidson's report on the microscopical changes was: 'The glomeruli are of very unequal size, some hypertrophied and others completely functionless and transformed into hyaline foci. Many of the glomeruli show the presence of homogeneous eosinophilic material, which does not stain for amyloid and presumably represents hyaline thickening of the glomerular capillaries. Some of the afferent arterioles show thickened walls in which the same eosinophilic hyaline material is present diminishing their lumina.' Figs 2 and 3 illustrate the pathology of the kidney.

In summary, this case showed diabetes of moderate severity for 17 years, with onset of hypertension and retinopathy after five years and of albuminuria after 14 years—low-grade subacute nephritis terminating in uraemia with oedema and the kidneys showing changes which are now described as intercapillary glomerulosclerosis.

#### Case 5

This patient, aged 59, visited the Eye Institute complaining of failing vision in February 1945, and a diagnosis of diabetic retinitis was made. Questioning elicited a history of polydipsia, polyuria, and neuritic pains of some months' duration, and she was referred to the diabetic clinic, where the diagnosis of diabetes mellitus was confirmed. At this time there was a trace of albumin in the urine. A diet of 1,500 calories was prescribed, and during the next year the patient's condition improved, the albuminuria disappeared and glycosuria was minimal.

On Jan 2, 1947, she was admitted to hospital with swelling of the legs and abdomen, fatigue, and frequency of micturition. She had not been adhering strictly to her diet. She was plethoric and dyspnoeic, but there was no cyanosis. The blood pressure was 250/110, with a pulse rate of 100. A small effusion was present at the right base, with bilateral basal rales. The heart was enlarged to the left clinically. The abdomen showed oedema of the abdominal wall and ascites. The liver edge though just palpable, was not tender. Fundal examination revealed macular changes and numerous haemorrhages—a diabetic retinopathy. A lens opacity was noted on the right side. The urine showed much sugar and albumin but no acetone, and microscopy revealed epithelial cells, pus cells, and granular casts. The blood sugar was 0.306%, blood urea 38 mg per 100 ml, plasma CO<sub>2</sub> 58 vols %, total plasma proteins 5.41 g %, with an A/G ratio 2.7/1. Radiograph of chest showed fluid at both bases.

Insulin, 15 units twice daily, was prescribed, and within one week the urine became sugar-free and the blood sugar fell to normal levels. The albuminuria persisted throughout the course of the illness and the oedema and ascites increased in spite of mercurial diuretics, paracentesis, and the intermittent application of Southey's tubes to legs and thighs. During April, 1947, 20 pints (11.36 litres) were withdrawn by these methods and in May, 1947, 42 pints (23.86 litres) were evacuated. The blood pressure remained high.

A urea concentration test was carried out on May 7 showing a maximum concentration of 1.3% with a standard clearance of 17%, and the blood urea rose slowly to 120 mg per 100 ml. The specific gravity of the urine varied from 1010 to 1020, and the urinary deposit always showed hyaline and granular casts and occasionally epithelial cells, pus cells, and red blood cells. The plasma CO<sub>2</sub> was continually between 52 and 61 vols %. The protein content of the oedema fluid was 0.7 g % initially, falling steadily to 0.47 g % on June 29. The A/G ratio of the plasma altered from 2.7/1 to 1.3/1 before the patient's death on July 19. Necropsy showed Kimmelstiel-Wilson lesions, Grade 3 nephrosclerosis and subacute nephritis (Figs 4 and 5).

#### Group 2

This group consists of three patients aged 28 to 38, all of whom developed diabetes in early life and complained

later of swelling of the feet and legs—during the course of pregnancy in Case 15. The clinical picture in the later stages, especially in that of Case 13, was very similar to that of Case 5, with diabetes, albuminuria, and hypoproteinaemia, the intense oedema requiring relief by Southey's

FIG 4—Case 5 Photomicrograph  $\times 260$  H and E

FIG 5—Case 5 Composite photomicrograph  $\times 140$  H and E

tubes and the ascites necessitating repeated paracentesis. The only real difference between the two cases was the absence of retinal haemorrhages and exudates in Case 13 and the lower blood-pressure readings during the later phases of the disease. The course taken after subacute nephritis supervened was similar to the history of that disease in the non-diabetic. So far as the diabetic state was concerned we gained the impression that the diabetes became less insistent (insulin dosage could be moderately reduced) and there was no tendency to the occurrence of diabetic acidosis. Case 13 is typical of this group.

### Case 13

The patient was 24 years old when the diagnosis of diabetes was first made in 1929, the blood sugar then being 0.302%. He was stabilized on a diet of 2,316 calories, with 10 units of insulin twice daily. He was observed at intervals until 1932, and during this period control was good, the urine being usually sugar-free. His weight was 161 lb (73 kg). In 1933

FIG 6—Showing progress of disease in Case 13

FIG 7—Case 13. Composite photomicrograph  $\times 140$ . Right half aniline blue, orange G. Left half H and E.

he had cervical adenitis and, later, an attack of shingles. For a short time thereafter the pulse rate was fast. Between 1934 and 1937 he continued to follow his work as a cabinet maker and his weight increased to 174 lb (78.93 kg).

In 1937 he complained of being easily tired and of weakness of the legs, and was admitted to hospital for observation. Diabetes was found to be well controlled on insulin, 32 units twice daily. There was no oedema, muscular weakness of the legs, or neurological phenomena. The fundus oculi was normal, the pulse rate 80, and the blood pressure 145/80. During 1937 and 1938 the patient was twice admitted to hospital with mild hypoglycaemia, and insulin was reduced from 36 units twice daily to 32 units twice daily. In 1939 his weight had increased to 182 lb (82.55 kg). In 1940 he had German measles, and a few months later developed transient arthritis of the fingers and wrists.

In 1941 he complained of swelling of his feet and was admitted to hospital. There was generalized oedema of a moderate degree. The urine showed much albumin, with a deposit containing epithelial casts. The blood urea was 45 mg per 100 ml, plasma protein 4.13 g %, plasma chloride 555 mg per 100 ml, and blood sugar 0.246%. The oedema disappeared with rest in bed and mild diuretics, and the albuminuria cleared a little later. Insulin dosage was reduced to 20 units twice daily. In 1942 albuminuria recurred with slight oedema. Renal function tests at this time showed urea concentration up to 31% and blood urea 31 mg per 100 ml. The albuminuria rapidly cleared on this occasion but recurred six months later, when the patient was again admitted to hospital (September, 1942) with generalized oedema. The blood pressure was 164/115, blood urea 64 mg per 100 ml, and the urine contained much albumin and a number of granular and hyaline casts and red blood cells. The plasma chloride was 526 mg per 100 ml and plasma protein 4.85 g %. Fundal examination showed no abnormality. Insulin dosage was 24 units twice daily. Various methods were tried to deal with the oedema, including mercurial diuretics and Southey's tubes. After six months his improvement was only moderate but he was allowed out of hospital, only to be readmitted later in 1943 with intense oedema which terminated in septic infection of the legs, pleural and ascitic effusions, pulmonary congestion, and terminal pneumonia. The course of the disease is presented graphically in Fig 6. Post mortem examination revealed evidence of subacute nephritis without K W lesions (Fig 7).

### Group 3

This group consists of six patients, all in the later decades with one exception, in these the history of the diabetic state is short, and the whole clinical picture of diabetes, hypertension, retinitis, albuminuria, and renal damage was already present when the cases first came under observation. So far as the clinical manifestations go they are indistinguishable from cases in Group 1 except for the short history of diabetes, but they may be quite different in pathogenesis, the whole picture, including diabetes, being the result of one degenerative process. Since this group is well recognized among clinicians it is deemed unnecessary to describe any case in detail.

### Group 4

In this group are three patients with a diabetic history and urinary infections resulting in pyelonephritis and renal failure. These cases are differentiated by the typical urinary findings, and should not be confused with groups already described.

### Summary of Pathological Findings

Pathological reports on the seven cases which came to necropsy are given below. Focal glomerular lesions of the type described by Kimmelstiel and Wilson are defined on the basis of the criteria suggested by Siegal and Allen (1941) and classified according to the method of Bell (1946), Grade 1 being scanty and Grade 3 frequent.

**Case 1** (Figs 2 and 3)—Both kidneys were enlarged (combined weight 450 g). The capsules stripped easily, leaving a

finely granular surface. The cortices were narrow and the small renal vessels thickened. *Histology*—"Foci of glomerulosclerosis alternate with areas in which there is proliferative glomerulitis. Capsular adhesions are numerous. The glomerular capillaries show hyaline thickening. The collecting tubules contain hyaline casts. Arteriosclerosis and hyaline arteriosclerosis are prominent. Lesions of Kimmelstiel-Wilson type (KW lesions), Grade 1. This is a case of subacute nephritis (associated with nephrotic oedema) probably occurring in a nephrosclerotic kidney."

*Case 3*—The kidneys were small with granular surfaces. The cortices were narrow. *Histology*—"There is severe glomerulosclerosis, much of which is recent, resembling a glomerulonecrosis in the process of hyalinization. Arteriosclerosis and hyaline arteriosclerosis are severe. Pyelonephritis is also present. KW lesions, Grade 1. This is the scarred kidney of a chronic nephritis."

*Case 5* (Figs 4 and 5)—The kidneys were enlarged (combined weight 530 g). The cortices were pale, the medullae congested. The capsules stripped readily. *Histology*—"There is a moderate degree of glomerulosclerosis. The surviving glomeruli show capsular adhesions and hyaline thickening of the capillaries. There is exudate in Bowman's spaces, partially organized in some glomeruli. The collecting tubules contain hyaline casts. Arteriosclerosis and hyaline arteriosclerosis are prominent. KW lesions, Grade 3. This is a case of subacute nephritis (associated with nephritic oedema) which has possibly occurred in a nephrosclerotic kidney."

*Case 6*—The kidneys were of normal size. The capsules stripped easily. There was no abnormality of renal architecture. *Histology*—"There is slight focal glomerular hyalinization. Arteriosclerosis is slight, arteriosclerosis is of moderate degree. KW lesions, Grade 2. This is a nephrosclerosis of trivial degree."

*Case 12*—The kidneys were reduced in size and the capsules were adherent. The surfaces were granular. *Histology*—"There is gross glomerulosclerosis, many glomeruli being only recently hyalinized. Interstitial fibrosis, arteriosclerosis, and hyaline arteriosclerosis are all severe. There is a concomitant pyelonephritis. KW lesions, Grade 3. This is a severe nephrosclerosis."

*Case 13* (Fig 7)—Both kidneys were enlarged (combined weight 420 g). The cortices were wide and pale. The medullae were congested. The capsules stripped easily. *Histology*—"The glomerular capillaries are thick, hyaline and patent. There are frequent capsular adhesions. There is no glomerulosclerosis, and arteriosclerosis and arteriosclerosis are both insignificant. The collecting tubules contain hyaline casts. KW lesions absent. This is a subacute nephritis (associated with nephrotic oedema)—histologically of the 'nephrosis' pattern."

*Case 23*—There was bilateral hydronephrosis, and abscesses were noted in the medulla of the left kidney. *Histology*—"Left kidney—pyelonephritis is marked. There is slight glomerular hyalinization and arteriosclerosis. Hyaline arteriosclerosis is severe. KW lesions, Grade 1. This is a severe pyelonephritis."

### Discussion

During the past decade increasing attention has been drawn to renal failure as a later complication in diabetes. The earlier publications on the subject were largely concerned with observations in post-mortem material of hyaline degenerative changes in the glomeruli of the kidney, to which Kimmelstiel and Wilson (1936) assigned the term "intercapillary glomerulosclerosis." With wider recognition of this condition, attention turned naturally to the clinical manifestations and their correlation with the pathological changes. Newburger and Peters (1939) described four cases showing diabetes, albuminuria, oedema, nitrogen retention, and retinopathy in which the clinical history was known and the typical hyalinization of renal glomeruli was found at necropsy. They also described five other cases, clinically similar, but without pathological confirmation.

Porter and Walker (1941) analysed the clinical and laboratory features of eight cases of intercapillary glomerulosclerosis where the diagnosis was verified in six instances. Albuminuria was severe, blood pressure usually over 200, blood proteins much reduced, oedema of significant degree, and anaemia, nitrogen retention, and retinal haemorrhages were prominent in this group. They suggested that the renal changes represented an instance of a predilective degenerative process in diabetes culminating in the syndrome described. Herbut (1941) reviewed 2,000 necropsies and found nine cases fulfilling all the requirements described and showing glomerular lesions. Albuminuria in these cases varied in amount in direct relation to the degree of oedema, while the occurrence of casts in the urine was unrelated to the presence of glomerular hyalinization. Siegal and Allen (1941) studied 105 diabetic necropsies and correlated the history of hypertension with the presence of glomerulosclerosis. In 60 cases without hypertension glomerulosclerosis occurred 12 times, in 27 with hypertension the lesion was found nine times, and in 18 with the complete renal syndrome glomerulosclerosis was present in 14.

Up to this point it would seem that the authors quoted tended to consider that intercapillary glomerulosclerosis was the cause of renal failure.

Horn and Smetana (1942) pointed out that, although glomerulosclerosis in its more advanced state was seen only in cases of diabetes, it was not of necessity associated with a particular clinical syndrome. Laipply and his co-authors (1944) studied the necropsy reports and clinical notes of 124 diabetic patients and recognized areas of glomerular hyalinization in 79 instances. In general the lesion was relative to the duration of diabetes in its occurrence and degree. Although in some cases hyaline degeneration was of less marked degree and although 64 patients showed albuminuria, the nephrotic syndrome occurred in only five of this series. This would cast some doubt upon the conception that glomerular hyaline degeneration is of prime aetiological significance in the pathology of renal failure in these conditions.

A new point of view was adopted by Bell (1946), who found that glomerulosclerosis was well correlated with arteriosclerosis. In 189 necropsies on patients with diabetes but without arteriosclerosis no glomerular lesions were found. In 148 diabetic cases with arteriosclerosis 67% showed hyaline glomerular lesions. He concluded that in most instances the degree of hyalinization was proportional to the severity of the arteriosclerotic changes.

It is obvious from the conclusions of previous authors that considerable difficulty arises in attempting to correlate clinical signs with pathological findings in this condition.

From the evidence presented in this paper it seems quite clear that, apart from surgical lesions of the renal tract, at least four types of renal failure may occur in the diabetic. The series in Group 1 corresponds closely to most of the material previously described. So far as post-mortem evidence goes in this group there exist in each case examined widespread pathological changes in the kidney, other than glomerulosclerosis of this type, which might result in uraemia. This leads us to conclude that diabetic glomerulosclerosis is in itself incidental and is not the primary cause of renal failure.

Cases in Group 3 show the same clinical picture but with this important difference, that widespread vascular changes and diabetes occur practically simultaneously. Owing to the absence of post-mortem proof it is impossible to say whether the typical pathological renal changes are in fact present. If further evidence shows that glomerular

hyaline degeneration is present in these cases—as is probable—it would seem that this degenerative change is not due to the diabetes itself but to associated vascular lesions. In any case we are of the opinion that widespread arterial degeneration can produce the whole clinical picture within a short space of time.

With regard to Group 2, where incidental oedematous nephritis occurred in diabetes, the differential diagnosis is practically impossible during life. The clinical picture is the same, with the exception of occurrence earlier in life and perhaps the absence of retinal haemorrhage.

**Prognosis**—The onset of albuminuria, apart from that associated with a precomatose state in diabetic patients, is usually of serious import and must be taken as a warning of impending renal complications. When retinitis and oedema occur the outlook is bad, and within two years death usually supervenes from uraemia, cardiac failure, or a combination of both. It is doubtful whether, in the present state of knowledge, any steps can be taken to defer these changes or to deal effectively with them when they occur.

### Summary

Twenty-four cases of renal failure occurring in diabetic patients are described.

Classification shows four groups including those associated with the Kimmelstiel-Wilson lesion.

Pathological details and photomicrographs illustrate the paper.

We are indebted to Mr Norman Mowat for preparing the composite photomicrographs and to Mr George Cheyne for technical help.

## DIABETIC COMA

BY

R. H. MICKS, MD, FRCPI

Physician St Patrick's Hospital

From Jan 1, 1940, to Jan 1, 1946, Root treated 188 cases of diabetic coma in the New England Deaconess Hospital with 6 deaths, and from Jan 1, 1946, to Jan 1, 1948, he treated 55 cases with no deaths. He has published a very full description of his methods of treatment (Root, 1945). My authority for the recent statistics is a personal communication from him. Few physicians or clinics have published their death rate in diabetic coma, and no recorded results are so good as this.

My essay in discipleship is prompted by the wish to make this line of treatment more widely known, for it has received sadly little attention from writers of textbooks in Europe, and some of the textbooks that are deservedly popular in this country advocate methods which include those very sins of commission and omission which Root has shown to be responsible for failure to save the more severe cases of coma. The chief sin of omission is not to appreciate the urgent need for large doses of insulin and the fact that insulin-resistance increases as the condition

progresses. The chief sins of commission are the early administration of glucose and the use of the oral route for the administration of fluids.

This paper is based on bitter personal experience, for I have made many mistakes myself, and have learnt what happens when sufficient insulin is not given soon enough, when gastric aspiration is omitted or fluids are given by mouth, and when glucose-saline is given intravenously instead of simple normal saline.

Undoubtedly much of the credit for the good results of Root and his colleagues must be given to their personal skill and to the 24-hour laboratory service maintained in their hospital. But even the worst cases can be saved by physicians of less experience and in the absence of blood analysis. Root (1945) states: "No plan of treatment based on mathematical calculations of the blood sugar and carbon dioxide will take the place of constant bedside observation of the patient and adjustment of treatment to the patient's changing condition."

### Nomenclature and Diagnosis

The accepted meaning of the word "coma" is a state in which the patient does not respond to any external stimulus. In this sense of the word the term "diabetic coma" is a misnomer, for it is only very rarely that the patient when first seen is in a state of true coma, usually the mental state is one of mild, moderate, or severe confusion with marked drowsiness.

The term diabetic coma is in fact by general agreement applied to severe rapidly progressive diabetic ketosis, and its diagnostic features are increasing drowsiness and confusion (ending eventually in true coma) with increasing hyperpnoea, dilatation of the stomach, and eventually circulatory failure due to electrolyte and water depletion. The biochemical findings are characteristic. It is readily induced even in the controlled diabetic by acute infections or alimentary tract disturbances. It is not so much a complication of diabetes as the end-stage of diabetes and the treatment of coma is the treatment of diabetes—namely, insulin.

The condition is easy to recognize, a mistake being in fact almost impossible. One essential feature which distinguishes it from other causes of coma in diabetics is that in diabetic coma "unconsciousness" does not supervene till after a progressive and characteristic illness lasting as a rule several days. The diabetic who is found "unconscious" without any preliminary illness may be a case of hypoglycaemia or he may have had a stroke, but he is certainly not a case of diabetic coma.

### Summary of Treatment

In most cases it is possible to bring about a striking improvement in from three to six hours, and during this period constant hard work at the bedside is necessary. The only factor in bringing about this improvement is insulin. Two other measures are important—gastric aspiration and the intravenous administration of normal saline.

The chief point in treatment is to ensure even at the risk of giving more than may be needed, that the patient gets enough insulin within the first three hours. Of course in many cases some infective process is present and must be treated too.

### Insulin Dosage

There are four points of fundamental importance. The first is that it is the insulin which cures diabetic coma though other measures are necessary they are not curative. The second point is that insulin resistance increases so long

as the coma remains inadequately treated, the longer the delay in administering an adequate dose the greater the dose required to cure the patient. The third point is one which is familiar to all physicians who treat diabetic coma, but is not sufficiently emphasized by textbooks. The beneficial effect of an *adequate* dose of insulin is clinically manifest as a rule in less than 15 minutes, if a single dose of insulin fails to produce an obvious improvement within about 15 minutes it may be inferred that the dose was grossly inadequate. The fourth point is also one which has not been emphasized strongly enough—that, if what may later prove to be an unnecessarily large dose be given, a lapse into hypoglycaemia is not to be feared until after the clinical improvement that is bound to follow a more than adequate dose has taken place.

The required dose varies greatly. In general, the longer the patient has been ill and the graver his state the higher the required dose, but it is impossible to know in advance how much will in fact be required. One gives repeated doses and watches the effect. In an early case—that is when the patient can give a clear account of himself—start with 100 units, and if there is no obvious improvement in half an hour give 100 units every half-hour until an improvement is obvious. Even in early cases a single dose of 100 units is usually not enough. If the patient is already drowsy and confused give the same initial dose of 100 units, but do not wait longer than a quarter of an hour before giving the second 100 units, for in a mentally confused patient the early good effect of an effective dose is very obvious. If the patient is inaccessible (“unconscious”) start with 500 units, and be prepared to give more if no improvement is seen at the end of half an hour. When the patient is a child a lower scale of dosage may be adopted, and very often hitherto untreated diabetics in coma need less insulin than long-established insulin-treated cases.

If at any stage a striking clinical improvement has occurred and steady progress is maintained, no further insulin need be given, but the moment any suspicion arises that the improvement is not continuing more insulin must be given. If a clinical relapse occurs—that is if the patient after a short improvement tends to revert to his original drowsiness—*very much more* insulin must be given.

If at the end of the first hour a very obvious improvement has not been produced it must be assumed that the dose of insulin so far given was not merely inadequate but grossly inadequate. It must be remembered that, although some severe cases recover on a few hundred units, dosages of about 1,000 units have sometimes to be given, and even 2,000 units have occasionally been required. Very large doses are particularly likely to be necessary for patients who have before admission been given glucose accompanied by insufficient insulin.

If no improvement has occurred by the end of the first hour doses of 100 units should be given as often as every ten minutes till improvement begins. The chief and most easily detected early signs of improvement are in the mental state and the hyperpnoea.

The less experienced a physician is in the treatment of diabetic coma the more generous should his dosage of insulin be, he must start treatment with the resolution that, whatever happens, he will not allow his patient to die from underdosage. A steadily falling blood sugar is a good indication that the dose so far given is adequate, and a physician who has to treat diabetic coma without blood-sugar estimations should make a point of erring on the generous side with his dosage. An even more trustworthy sign of adequacy of dosage is a steady mental improvement and diminution of hyperpnoea, but the less experienced

physician may find it difficult to be sure that the expected improvement has started. If he is in doubt he should play for safety by giving more insulin, and thus he may expect to find later that he has given much more than was really needed.

So when diabetic coma is treated without blood-sugar control or by relatively inexperienced physicians some cases of hypoglycaemia may be expected to occur, but hypoglycaemia is a minor complication and very easy to deal with. Usually it does not occur until the patient is able to take food by the mouth, but in any case it is easily corrected by an ampoule of concentrated glucose solution intravenously. So far as I know there is no record of a patient ever having passed from diabetic coma into a fatal hypoglycaemic attack.

At the end of three hours there should be marked improvement. The hyperpnoea should have stopped, the blood-sugar should have fallen to near normal, and in many cases the urine will be sugar-free. The pulse rate will nearly always still be rapid. In some cases there will be very much less acetone in the urine, but the rate of improvement in Rothera's test is variable. If the urine was originally copious and pale it should have become less copious and more concentrated. If the urine was scanty or absent (as in extreme cases with grave circulatory failure) the administration of saline should have begun to produce a normal urinary secretion. If the patient is unable to pass urine one must never hesitate about catheterizing at hourly intervals in order to obtain a specimen.

If at the end of the first three hours a striking change for the better has not taken place the sands are running out, and the dosage of insulin must be condemned as very grossly inadequate and very much more be given.

In nearly every case at the end of the first six hours the patient is ready to eat and drink and is asserting his improvement with delight. In the young patient everything should now go smoothly, provided that a watch is kept for hypoglycaemia. In elderly or debilitated patients difficulties in the restoration of the water and electrolyte content of the body fluids may arise.

Relapse into diabetic coma is very rare indeed, but the dosage of insulin required during the few days after recovery is very variable. Many cases, after being sugar-free and almost acetone-free, soon develop glycosuria and slight ketonuria again and need large doses for the next few days, but others may not need any insulin at all for twelve or twenty-four hours after their recovery.

### Gastric Aspiration

In almost every case of diabetic coma admitted to hospital the stomach is dilated, and unless this is dealt with the physician will lose some of his cases no matter how skilful his treatment in other respects may be. In many cases the condition gives rise to abdominal pain, but in others there is no complaint of pain at all. Examination of the abdominal wall does not as a rule give any hint of the presence of this dilatation.

As soon as the initial dose of insulin has been given a stomach-tube should be passed no matter how strongly the patient may object. Usually at least a pint of contents can be aspirated, and in all cases of severe coma they are black, in the less advanced cases they are brown or pink, but sometimes at an early stage they are not tinged with blood at all.

When gastric aspiration is omitted the following sequence of events may occur. Improvement on insulin and intravenous saline takes place and the patient seems to be on the

road to recovery Then, as his mental state improves, just as in a patient recovering from an anaesthetic, he becomes restless, vomits a few ounces of black or coffee-coloured fluid, and within a few minutes marked dyspnoea with numerous rales sets in, the pulse becomes quick and feeble, and the patient dies in cyanosis Post-mortem examination shows gastric contents in the respiratory passages

Unless the patient is mistakenly allowed to drink before he has recovered it is not usually necessary to aspirate the gastric contents a second time, but a second aspiration is occasionally called for A return of abdominal pain or a rising pulse rate should suggest the need for a second aspiration

It should be remembered that the disturbance of the alimentary tract is not confined to the stomach The intestine is often incapable of absorbing a rectal drip, and a rectal saline may be retained in the bowel for some hours before being returned

### Saline

Almost every case of moderately severe diabetic coma needs (if an adult) from 2 to 4 litres of normal saline in the first few hours If the blood pressure has fallen to a dangerously low level 2 litres given quickly will as a rule restore it, but much more may be needed In rare cases with complete anuria even larger volumes have been given with success Root emphasizes that in such cases intravenous saline should be given until urinary excretion begins

It is not easy to know which cases will need intravenous saline and which will recover without it Except in cases of marked circulatory collapse it is not an urgent matter, but once the patient has reached hospital it is wise to give it if the case is of even moderate severity The needle used should be of a bore large enough to allow a rapid flow, but in cases with circulatory failure it may be necessary to cut down a vein Another difficulty sometimes met with is vein spasm In such cases a pump of the rotating cam type which milks the fluid down the tube can be used to start the flow, once spasm has been overcome it is no longer needed In gravely collapsed patients subcutaneous saline should be started at once in order that no time shall be lost while search for a vein is being made

The rate of flow should be fast enough to deliver the initial 2 litres in about an hour In some cases it may be possible to stop then, but as a rule it is safer to leave the needle in for a few more hours and continue to administer at least enough saline to make good the continuing urinary loss until clear clinical signs of recovery appear There is no risk of overloading the circulation by the initial 2 litres, but in elderly diabetics with myocardial inadequacy and potential left-ventricle failure there is a grave risk of delivering fluid too rapidly after the initial extreme sodium and water depletion has been corrected In children the rate of flow must be much slower than in adults

Root's statistics strongly support his claim that normal saline is the only intravenous injection needed in diabetic coma Other authors have asserted that alkalinizing solutions are necessary or that plasma should be used Any physician who has seen elderly diabetics pass the first critical six hours and become sugar-free and ketone-free only to die a few days later from circulatory failure must worry, as I have done, about the adequacy of his treatment But, in view of the very large volume of saline given by Root to some of his cases with ultimate success, the probability is that when others fail to restore the blood volume it is the physician's judgment which is at fault and not the composition of the solution used

Recently it has been pointed out that recovery from diabetic coma is followed by a fall in blood potassium and

blood phosphate levels, and it has been suggested that this fall may be the cause of deaths occurring some hours or days after the cure of the ketosis

There is, in effect, definite evidence that a serious potassium depletion may occur in some cases, and the clinical picture appears to be recognizable If marked asthenia follows an apparent clinical recovery the possibility should be suspected and potassium chloride (or some other potassium salt) given in 0.5-g doses every half-hour Recovery has been recorded as a result of this line of treatment (Holler, 1946, Nicholson and Branning, 1947)

### Glucose

For some years Root and his colleagues have preached against the administration of glucose in diabetic coma Their arguments have been so widely accepted, and they have made so many converts among those who formerly administered glucose as a routine, that it must be admitted that they are right

There is of course no danger in administering glucose if after a successful treatment by insulin a low blood sugar or sugar-free urine suggests that hypoglycaemia is to be expected, but glucose given at an earlier stage is dangerous Admittedly many cases of coma which have been given glucose and sufficient insulin have recovered, but nevertheless glucose given at an early stage exposes the patient to special added risks which may just turn the scale against him

Glucose-saline must not be given instead of normal saline by the intravenous route One litre of glucose-saline contains 50 g of glucose—that is, enough glucose to raise the already very high blood sugar to well over 1% if the injection is given at the usual rate As a result the urinary excretion of water and of glucose tends to rise rapidly, and the degree of both water and sodium depletion may be increased Almost as serious is another result—that the physician is deprived of two very valuable aids to his assessment of progress, the falling blood sugar and the gradual return of the volume and colour of the urine to normal Finally it has been shown that continued administration of glucose may in the end favour the onset of anuria

The notion that glucose is a part of the treatment of coma entails another danger—that the physician may order his patient to drink glucose solution and thus increase the degree of dilatation of the stomach In my experience this is a very common mistake, and the ill effects are very obvious

### The General Practitioner and Coma

Few of us can hope to be in a position to claim, like Root, that we have cured 55 consecutive cases out of 55, but all of us should be able to cure every moderately early case The following suggestions should facilitate early administration of insulin, the point above all others which is decisive

Every patient on one of the slow insulins should stock a couple of bottles of plain insulin for his doctor's use in emergencies, for the doctor called to a diabetic's house may not think it necessary to pack insulin in his bag

Every hospital which is prepared to treat diabetic coma should make it known to all local practitioners and to all its diabetic patients that an acutely ill diabetic is always admitted without even telephone notice, whether it has a vacant bed or not The relatives of all diabetic patients should know that when a diabetic takes to his bed or seems in any way unwell he should be shifted at once to hospital

The doctor called to a case of coma should always give at least 100 units at once before even ordering the ambulance If the patient is inaccessible ("unconscious") he should give

500 units, but in such patients he should aspirate the gastric contents, as extreme gastric dilatation is sure to be present and the patient may improve enough to vomit in the ambulance and inspire his vomit

Any physician who has ever treated diabetic coma in the patient's own home must agree that, though of course one may succeed, the difficulties are so great and the unpleasant surprises so numerous that home treatment should rarely if ever be undertaken

### Summary

The line of treatment of diabetic coma given by Root and his colleagues in Boston is advocated

The essential point is large insulin dosage at an early stage. Physicians less experienced than Root and working in less well-equipped clinics should deliberately err on the side of giving larger doses than the experts, for there is no danger in giving too much and every danger in giving too little

Gastric aspiration must be carried out as routine in every case and nothing be given by the mouth during the critical first few hours

Intravenous saline is needed by many cases and by all the severe cases, sometimes in very large quantities. The syndrome of potassium depletion must be rare, but the possibility should be kept in mind

Glucose must not be given by any route until clinical recovery has been achieved, but after this it may safely be given to prevent hypoglycaemic attacks

## TREATMENT OF CHRONIC VARICOSE ULCERS BY LUMBAR SYMPATHECTOMY

BY

JOHN BORRIE, MB, Ch B N Z, FRCS

AND

E VERNON BARLING, MB, B S Sydney, FRCS  
 FRACS

(From the General Hospital Southend-on-Sea)

Chronic varicose ulcers heal slowly, relapse easily, and remain a source of constant annoyance to those they affect. Some tend to heal in summer, some with or in spite of the application of lotio rubra, scarlet red, sulphonamide, or penicillin powders, some following protection by Unna's paste or "elastoplast", some respond to sclerosing treatment of the causative veins or after Trendelenburg's operation with high and low ties, some even requiring skin-grafting. Yet many, even after this gamut of medical and surgical treatment, remain a chronic antisocial disability to their unfortunate owners

### Case 1

A man aged 49 was admitted to Southend General Hospital on Sept 9, 1946, with a history of varicose veins in his left leg associated with a large left varicose ulcer for 27 years. He had had a flesh gunshot wound in this leg below the knee in 1917, without peripheral nerve injury. In 1937 a left saphena varix had been excised. In spite of a wide range of local treatment the ulcer never healed even after lengthy periods of rest in bed. The Wassermann reaction was negative

On June 8, 1946, two varices were excised from the left femoral triangle and several others from the left popliteal fossa. On reporting to the out-patient department on Aug 17 he complained of the ulcer, which was larger than before,

together with pain and swelling in the left leg. There was thrombophlebitis of the branches of the saphena magna vein. On Sept 9, there being no improvement, he was admitted. The ulcer, situated just above the medial malleolus, measured 5 by 3 cm

The leg was elevated and the ulcer covered with tulle gras. Sulphadiazine, 14 g, was given orally for two days. The swelling rapidly subsided and the phlebitis regressed, but the ulcer remained the same. Its cure became the next problem, for it greatly handicapped him in his work as a painter

On examining him afresh what impressed us most was the coldness of the limb, together with its cyanotic appearance compared with his normal right leg. The cutaneous circulation was obviously poor. It occurred to us that, if only the blood supply to the skin could be improved, healing of the ulcer might occur spontaneously. The ulcer maintained its existence as a result of the state of stagnant anoxia which surrounded it. Almost it was an "anoxic ulcer". Arguing on the analogy that head wounds, with a rich blood supply, heal quickly and remain healed, we decided to try the effect of a lumbar paravertebral block of the sympathetic nervous system in improving the cutaneous circulation. Following the infiltration of 100 ml of 0.5% procaine solution along the left side of the lumbar vertebral column there was a remarkable improvement in the colour and warmth of the limb which persisted for 24 hours. As we did not have a skin thermometer the exact temperature rise could not be measured, but the patient had no doubt at all that his left leg was warmer

**Operation**—After considerable thought, in view of the attendant risks of any operation, we suggested that his ulcer might be "cured" by left lumbar sympathectomy. So far as we were aware at that time, this had not been tried for varicose ulcer before. It was an experiment, and we could not guarantee the result. The patient accepted. On Sept 27 left lumbar ganglionectomy was successfully performed, the second, third, and fourth lumbar ganglia being removed. In the left leg there was an immediate rise in temperature, which has persisted

Fourteen days after operation the ulcer was healed for the first time in 27 years. When seen on June 7, 1947, he was extremely fit and well, the skin was healthy, the scar soft. He said he felt ten years younger. On Sept 11 his leg was still healed. No pulse difference was detected in the femoral, anterior, or posterior tibial vessels of the right and left legs. To prevent swelling he wears a below-knee elastic stocking. On May 13, 1948, he reported that the ulcer was still soundly healed

### Case 2

A married woman aged 57 was admitted on Dec 31, 1946, with a left varicose ulcer which had persisted for 15 years, it being the result of a left "white leg". Three years after onset of the ulcer she developed "phlebitis" in her left leg following injection treatment for varicose veins. On Nov 13, 1945, one vein was tied below the left knee, with slight improvement in the ulcer and surrounding weeping eczema

Physical examination showed a fit corpulent woman. On the medial surface of the left leg were two chronic ulcers, each 4 by 2.5 cm, surrounded by a large area of weeping eczema and pigmentation extending half-way up the leg, which was cold and blue. There were no large varicose veins now. Her Wassermann and Kahn reactions were negative, and her urine was normal. She was finding the leg an increasing source of annoyance. After a left paravertebral block there was marked vasodilatation

On Jan 3, 1947, a left lumbar sympathectomy was performed. By Jan 16 the ulcer had healed for the first time in 15 years. The patient was discharged with instructions to apply calamine lotion to the varicose eczema and to keep the skin protected with a crepe bandage. When seen on June 7 her ulcer was soundly healed and the skin healthy. She said that eczema still occasionally bothered her. When seen on Sept 11 the eczema, which was some distance from the healed ulcer, was weeping. The ulcer had healed leaving a thick scar, which later might well be excised and skin-grafted. No elastic support had been worn, but one was on order. On May 18, 1948,

Table of Results

Case No	Sex	Age	Duration of Ulcer	Past Surgical Treatment	Size of Ulcer	Para vertebral Block	Lumbar Ganglion ectomy	Healed	Follow up
1	M	49	27 years	1937 left saphena varix excised 8/6/46 2 varices in left femoral triangle excised Deep thrombosis	5 x 3 cm	Good response	27/9/46 L 2-4	11/10/46	13/5/48 healed Wearing elastic
2	F	57	15 years	13/11/45 one varix tied below knee	4 x 2.5 cm	Good response	3/1/47 L 2-4	16/1/47	11/9/47 ulcer healed Eczema persists 18/5/48 eczema healed Ulcer broke down Leg still warm Wearing elastic stocking
3	F	71	39 years	17/1/46 left Trendelenburg	4 x 1.5 cm	Good response	21/2/47 L 2-4	14/3/47	18/5/48 healed Wearing elastic stocking
4	F	56	16 years	23/10/46 bilateral Trendelenburg	7 x 4 cm	Good response	22/5/47 L 2-4	5/6/47	11/9/47 ulcer healed Some eczema 8/5/48 ulcer healed and skin dry Wear ing elastic stocking

she wrote that the left leg was still warmer than the right, the eczema was healed, but the ulcer had broken down again, and she was now wearing an elastic stocking

### Case 3

A married woman aged 71 was admitted as an 'emergency' on Feb 18, 1947, suffering from the recent onset of a patch of superficial dry gangrene on the ball of her left foot. She had suffered from bilateral varicose veins and a left chronic varicose ulcer for 39 years. On Jan 17, 1946, a left Trendelenburg operation, with low ties, was performed, with no improvement. On Feb 12, 1947, she complained of the chronicity of the ulcer and of "something wrong" on the sole of her foot which made her limp. This was a source of great inconvenience, as she kept house for an invalid sister aged 76.

On examination the left leg was cold and blue, with a deep chronic ulcer 4 by 1.5 cm extending down to the left medial malleolus. There was pronounced scarring of the surrounding tissue with resulting acquired pes cavus. On the ball of the great toe was a patch of superficial dry gangrene 2.5 cm in diameter. The left posterior tibial pulse under scar tissue was impalpable, the other pulses being present in the right and left legs. The legs were otherwise normal. The Wassermann and Kahn reactions were negative. The haemoglobin was 89%, the blood urea 28 mg per 100 ml, and blood sugar 81 mg per 100 ml. Her urine was normal. A radiograph of her legs showed no vascular calcification.

As there was good response to paravertebral block, on Feb 21, 1947, left lumbar ganglionectomy was performed. There was a dramatic response, the lesion of the sole healing in two weeks. Simultaneously the varicose ulcer improved, being healed in three weeks from the time of operation—the first time in 39 years. When seen on June 7 both areas were soundly healed and the left leg was still warmer than the right. There was now no difficulty in walking. On Sept 11 her leg and sole were still healed. She wears an elastic stocking, without which the left leg swells. On May 18 1948 she wrote that her leg was still healed.

### Case 4

A married woman aged 56 had suffered from bilateral varicose veins for 19 years and a large varicose ulcer with extensive surrounding eczema for 16 years. There was no history of "white leg". The skin had been unsuccessfully treated with many local applications. On Oct 23, 1946, a bilateral Trendelenburg operation was performed without healing of the ulcer, which became covered with hard crusts. The eczema continued to weep.

On examination she was seen to be a large, heavily built woman. The right leg was soundly healed, no varicose veins being obvious. The lower half of the left leg was covered with a weeping varicose eczema. Under thick crusts above the medial malleolus was an unhealed ulcerating area approximately 7 by 4 cm. Though the leg was distally cold and blue the pulses were normal. There was a good cutaneous response to paravertebral block. Meanwhile the skin was treated with eusol compresses.

On May 22 a left lumbar ganglionectomy was performed. As a result the eczema dried and the patient was discharged on June 5 with the ulcer healed.

When seen on Sept 11 the ulcer was still healed, but superficial eczema remained. At times it wept, at times it was dry. There was no swelling of the leg. The pulses on her leg appeared normal, and there was no recurrence of the varicose veins. She had an elastic support on order. On May 8, 1948 she wrote that the leg had been dry since October, 1947. She still wore an elastic stocking.

### Discussion

As Richter (1941) rightly says, varicose ulcers can unquestionably be cured by many methods, and as sure as a sufferer has an ulcer, so his doctor has his own remedy. It is a question of *chacun à son goût*. Essentially, however, one treats the cause, which in the above case was the result of long-treated varicose veins where, though the veins had disappeared after a combination of ligation and thrombophlebitis, the cold cyanotic limb and ulcer remained. Infection played a secondary part in the maintenance of the ulcer. Only because all non-operative and all available operative procedures had failed was sympathectomy considered. In Case 3 an early gangrene of the limb was the reason for operation. The varicose ulcer which simultaneously healed was an interesting and instructive incident.

In his masterly review of the aetiology and treatment of varicose ulcers of the leg Homans (1917) divided ulcers into three groups: (1) ulcers of surface varix, (2) ulcers of surface varix complicated by varicosity of the perforating veins of non-inflammatory origin, and (3) same as Group 2 but post-phlebitic in origin. Groups 1 and 2 differ little except that, whereas the ulcer of Group 1 is near the principal superficial veins of the leg, the ulcer of Group 2 not only rides upon the large veins but tends to appear in the region of the perforating veins. Ulcers of Group 3 are decidedly different. They arise on phlebitis following childbirth, fevers, and operations. The valves of the veins are permanently incompetent. After the inflammation there are changes in the leg, with induration of fat and scarring of deep fascia, thus crippling the local lymphatic system, with resulting oedema. The ulcers tend to be rapid in onset, particularly chronic, bear no relation to visible veins, and have little or no tendency to heal even with rest in bed. We feel that Cases 1 and 2 finally belonged to Group 3, while Cases 3 and 4 were probably Group 2. In cases such as these Homans ligated the varicose veins first, and if no healing occurred he excised the ulcer and skin-grafted the raw area.

Some workers have used lumbar sympathectomy as a means of curing chronic varicose ulcers. The South Americans were early in the field. Gordon (1940) condemns its use, having had ten cases each of which showed initial prompt healing but nine of which recurred in less than one year. He favours excision of deep fascia of leg together with a thick Thiersch graft if the overlying covering is poor.

Gravelle and O'Donnell (1946) in a review of 21 cases of which six had stasis ulcers in contrast to arteriolar and traumatic ulcers, found all the results were "good"—the longest follow-up period being 18 months

Adams (1942) writes "There are two types of varicose ulcers that are particularly benefited by lumbar sympathectomy in addition to indicated therapy of the forms already enumerated. One is seen in the constantly moist sweating leg in which fungous infection is uncontrollable by medical measures. Sympathectomy abolishes the sudomotor activity, makes the skin dry and warm allows fungous infection to be controlled and healing to be maintained. The other type is characterized by multiple punched-out circular ulcers on brawny, cyanotic legs secondary to deep obliterative thrombophlebitis. Although peripheral pulsations may be present and of good quality, a glance at the leg is convincing evidence that the tissue circulation is inadequate to meet its metabolic needs, and hence the ulceration has occurred. Venospasm, lymphatic blockage, and postural stasis all may be contributing factors. The important practical fact, however, is that sympathectomy, by relaxing the spasm and improving the collateral circulation, will sometimes bring healing in this distressing group of cases that we otherwise have been forced to admit are incurable by any methods at our command."

The most arresting fact in our series was the rapidity with which the ulcers, present from 15 to 39 years, healed within three weeks and remained healed throughout two winters.

In choosing the method of treatment for recurrent varicose ulcer of the leg it is essential to consider the patient's economic status and the nature of his work. There is no doubt that many find a chronic ulcer a debilitating condition. Young people, especially men, can ill afford to continue losing time and efficiency. Every effort should be made to heal these ulcers quickly, and if sympathetic surgery is indicated it should be tried.

Homans observed that, even after the ulcers had apparently healed with skin-grafting, the grafts sometimes separated when the patient walked again. Cyanosis of the graft and oedema of the ankle were his danger signs. He therefore advised three weeks' post-operative rest in bed, with active and passive leg exercises besides massage, before the patient was allowed up.

Battle (1947), discussing the results of his series treated by skin-graft, likewise mentioned that several cases which at first appeared to have successful "takes" broke down soon after walking was recommenced, usually within six weeks of operation. Surely the answer to this failure is that skin-grafting, like tree-transplanting, requires suitable soil. If the ground is waterlogged and stagnant a tree transplanted there dies. So, too, did these grafts. We believe that with such patients the correct approach might well be first to improve the peripheral circulation by lumbar sympathectomy and then to graft the skin on a favourable "soil." We believe, too, that the wearing of an elastic bandage post-operatively to be very important. It protects the skin from trauma without and from oedema within.

One may well ask, Is such a condition really worthy of such attention and such treatment? The answer, we believe is yes. If these already overtreated ulcers can be healed permanently by this method or by combining it with fascial excision and skin-grafting—and the answer, as with all "cures," still lies a lifetime down the years—then will be removed another source of chronic disability and loss of manpower from humanity. One thing however, is certain—nothing is so profound as the heartfelt gratitude of three of these four people on being thus far released from the tedium of chronic discharging septic sores on their legs.

## Summary and Conclusions

Varicose ulcers may fail to heal even after the entire gamut of usual medical and surgical treatment.

Four such patients, with ulcers present from 15 to 39 years, were found to have cold blue limbs which responded by cutaneous vasodilatation to lumbar paravertebral block.

After lumbar sympathectomy these ulcers healed within three weeks. In three cases they have remained healed.

The value of lumbar sympathectomy in providing an adequate circulation to assist healing is thus demonstrated and its use before skin-grafting suggested.

The importance of continuing to wear an elastic stocking after treatment to protect the skin from trauma from without and oedema from within is stressed.

We wish to thank Mr Rodney Mamgot for his encouragement in this work and for his permission to publish these case reports.

## Medical Memoranda

### Twin Pregnancy with Acute Hydramnios Treated by Paracentesis Uteri

The following is a report of a case of acute hydramnios occurring in a twin pregnancy and resulting in the birth of one live twin and one foetus papyraceus after treatment by abdominal paracentesis uteri.

#### CASE REPORT

The patient, a multiparous gipsy aged 25, was admitted to hospital on May 18, 1947, on account of acute hydramnios. Her last menstrual period had begun on Nov 13, 1946, but instead of being six months in size the uterus had the dimensions of a full term pregnancy. There was a history of sudden abdominal enlargement with discomfort for the past few days, and of severe abdominal pain during the 24 hours preceding admission. The foetal heart sounds could not be heard, and parts were difficult to identify, although external ballotement was just possible. The patient was in considerable pain, requiring an injection of morphine a few hours after admission. The uterus, though distended, tense and tender, was not "board-like" as in concealed ante partum haemorrhage, and it was concluded that the excessive uterine enlargement was due to hydramnios. The temperature was normal (and remained so throughout the patient's stay in hospital), but the pulse rate varied from 90 to 130.

Further investigations revealed mild anaemia (Hb, 75%) and negative Wassermann and Kahn reactions. The blood group was B (III), Rh positive, the blood pressure was 115/85. The urine contained a trace of albumin but no casts or blood cells, and was sterile on culture. Radiological examination revealed a twin pregnancy, with the infants probably of no more than 28 weeks' maturity, one presenting by the vertex and the other by the breech.

The first paracentesis uteri was performed on the day after admission, when 4 pints 16 oz (2.73 litres) of clear liquor amnii was released. Subsequently the patient felt much more comfortable, with the pulse rate stationary at 92-96. A week later the procedure was repeated and 3 pints 2 oz (1.76 litres) of liquor

was withdrawn. In a third aspiration, on June 1, a further 3 pints 15 oz (2.13 litres) was drained, making a total of 11 pints 13 oz (6.62 litres) removed in three weekly sessions. By that time the patient was very well and fit to be discharged from hospital. The foetal heart sounds could now be heard distinctly, although it was not possible to distinguish between two separate hearts.

During the remainder of the pregnancy the woman was seen regularly in the antenatal clinic. She remained in good health, and there was no recurrence of the hydramnios. It was, however, noticed (and confirmed by x-ray examination) that one foetus failed to grow while the other seemed to develop normally. Spontaneous delivery of uniovular twins occurred at full term on Aug. 22: the first was a living female child weighing 6 lb 6 oz (2.89 kg) (vertex delivery) and the second a foetus papyraceus, 12 in (30 cm) long and weighing 11 oz (312 g). There was one large placenta, about a third of which was infarcted and had obviously not been functioning for some time. The living infant was perfectly healthy, and her progress, like her mother's, was uneventful, both being discharged from hospital on Sept. 1.

#### COMMENT

Puncture of the uterus through the abdominal wall in an effort to reduce the amount of liquor amni without terminating pregnancy was first advocated by Schatz (1918) and carried out by Henkel (1919) and Wormser (1920). Textbooks of obstetrics hardly mention the method and generally give a poor prognosis for the foetus in acute hydramnios. DeLee (1943) states that 'aspiration confers only temporary benefit,' and Taussig (1927) is of a similar opinion. The procedure was advocated in this country by the late Mr. Carnac Rivett (1933), who referred to it as 'a rational method of treating hydramnios, since in all cases sufficiently acute to demand interference any other line of treatment would result in a miscarriage or the birth of a barely viable child.' He found, however, that even in acute hydramnios the liquor is not under pressure and has to be sucked out. This was certainly not my experience in the above case or in several others in which liquor always drained freely as soon as the cannula was inserted.

The above case resembles those reported by Lloyd (1943) and by Erskine (1944) in that one twin survived while the other died *in utero*. It is submitted that by no other method of treatment could a living mature infant have been obtained in the case described. It is uncertain which of the two gestation sacs was hydramniotic, but it is tempting to argue that the hydramnios failed to recur because of the death of the foetus in whose bag the liquor had previously accumulated. In some cases there is indeed a recurrence of the hydramnios, and it is this observation which has brought the method of abdominal aspiration into disrepute. There is, however, no objection to repeating the process, provided that x-ray examination has failed to show a foetal abnormality. If there is a malformation present surgical induction of labour per vaginam is indicated, and paracentesis uteri can have no place in the management of such a case.

This report is published by courtesy of Mr. David Maxwell, under whose care the patient was admitted and who encouraged me to record the case.

### Intestinal Obstruction Caused by Faecalith

It is unusual for faecaliths to form in the small intestine. The size of the foreign object and the circumstances of its formation in the following case are worthy of record.

#### CASE REPORT

An ironworker aged 57 was admitted to the Royal Infirmary, Glasgow, on Jan. 22, 1947, complaining of lower abdominal pain of five hours' duration. The pain came on suddenly and was colicky in nature. It was felt mainly in the left iliac fossa, but periodically it passed to the epigastrium. There was no vomiting before admission and the bowels had moved that day. His history revealed no indication of disease apart from some digestive upset described as

an 'attack of the bile' occurring three years before and three days. This was the only illness which had kept him off work in twenty years.

On examination he was thin and looked moderately ill. The tongue was clean and moist. The abdomen was somewhat full in the right iliac fossa and there was some guarding in the left abdomen. Tenderness was present over the whole lower abdomen. Rectal examination revealed no abnormality. Conservative treatment was instituted, with limitation of diet to fluids, and an enema was given. Next day he felt better, but he began to vomit in the late afternoon and the pain recurred with greater severity. Slight dis-

FIG. 1—The specimen after section, showing the core of faeces and the covering of soaps.

tension was noted over the left side of the abdomen. By the morning of Jan. 24, obstructive signs were becoming evident. Vomiting continued, he began to become dehydrated, and the severe colicky pain persisted.

His abdomen was opened by a right gridiron incision on the 24th. A stony hard mass was felt in the terminal ileum about 15 in (37.5 cm) from the ileocaecal valve. The mass could easily be milked up the bowel, which was distended above it. Enterotomy

FIG. 2—Radiograph of the stone after removal.

was performed some above the obstructed area and a triangular stone was removed measuring 2 in (5 cm) along sides and 1 in (2.5 cm) in thickness (Fig. 1). A radiograph of the stone after removal (Fig. 2) showed a translucent core with a layer of opaque material round it. On section the calculus was found to have a soft centre of faeces surrounded by a layer of hard chalky material 3 mm thick. Analysis showed the outer material to be calcium soaps. The patient made an uninterrupted recovery.

On Feb. 21 he returned for barium examination of the intestinal tract. This showed no diverticula of the duodeno-jejunal region. In any of these a faecalith might have formed. No other faecaliths were noted.

#### COMMENT

It seems that this man had been developing a faecalith for some considerable time in a large diverticulum of the duodeno-jejunal region. It had caused no symptoms until, for some reason, it dislodged into the lumen of the intestine and passed along it to the comparatively narrow ileum. There it caused obstruction. I have been unable to trace in the literature any other case of this complication of diverticulosis in this region.

I am indebted to Mr. Donald Hay for the photographs.

ARCHIBALD L. GOODALL M.D., F.R.C.S. Ed.,  
F.R.F.P.S.G. DPH.

The Association for Hospital Services, which has now moved to larger accommodation at Tavistock House (South), Tavistock Square, London, W.C.1, has issued a pamphlet on its activities from 1941 to 1948 entitled *The Hospital Service Plan*. It includes a from H.R.H. the Duke of Gloucester congratulating the Association on its expansion and wishing continued success. The Association runs a contributory scheme to help middle class men and pay for accommodation in hospital beds or in private homes when they fall sick, and Dr. Russell Brain, chairman of the council, points out that the need for such a scheme will continue under the N.H.S. Sir Cecil Wakeley has recently joined the council.

## Reviews

### PENICILLIN FOR SYPHILIS

*Penicillin in Syphilis* By Joseph Earle Moore, M.D. (Pp 319, 57 figures, 27s 6d.) Oxford: Blackwell Scientific Publications, Ltd. 1947

This book may suitably be regarded as a supplement to *The Modern Treatment of Syphilis* by the same author for he discusses the application of penicillin to, and its value in, all forms of syphilis. He considers in turn the chemistry, pharmacology, and toxicity of penicillin, its effect on experimental syphilis and its mode of action, then its use in the various stages and forms of syphilis with and without arsenic, bismuth, and fever. Very rightly he stresses the possible confusion caused by using the antibiotic in other conditions and the absolute necessity of a careful follow-up after penicillin therapy. This work bears the imprint of authority, for Earle Moore has probably treated more cases of syphilis with penicillin than almost anyone and his figures are founded on vast numbers of patients treated on various schedules in numerous clinics in the U.S.A. The lists of references, suitably placed at the end of each chapter, are most useful and cover the period up to October, 1946. Much has happened since then, but, as he points out, if it were necessary to wait till finality had been reached the book would never have been written. The vast majority of the references naturally are to American authors, the names of Fleming and Florey merely receive passing notice.

Perhaps what will strike the reader most is the remarkable efficacy of penicillin in the treatment of the syphilitic pregnant woman and of early congenital syphilis. The original hopes of its effect in early acquired syphilis have been rather dashed by the number of relapses, yet it appears that it is still the fashion in the U.S.A. to rely on penicillin alone in early syphilis except in relapsed cases, whereas in Great Britain the concurrent use of arsenic and bismuth was adopted some years ago both in civilian V.D. treatment centres and in the Services. Perhaps one of the most interesting features of this book is the account of the beneficial effect of penicillin in various comparatively rare conditions which the average syphilologist sees only occasionally, such as optic atrophy, iritis, and nephrosis to mention only three, while the favourable effect of locally applied penicillin in interstitial keratitis will encourage those who often almost despair of obtaining any amelioration of an apparently intractable condition.

The question of the possible danger of Herxheimer reactions in certain conditions such as cardiovascular syphilis is well worth noting, and the careful physician will start treatment with very small doses such as 1,000 or even 500 units in these cases. It is good to hear on such authority that penicillin resistance is little to be feared, but the effect of the antibiotic on serum reactions is somewhat disappointing. We note that, contrary to statements by some authorities in Great Britain, the author considers penicillin plus malaria to be distinctly more effective than penicillin alone in symptomatic neurosyphilis and in optic atrophy. The production of this book is excellent and does credit to both author and publishers. There are many figures and tables and a few photographs. The final chapter is on streptomycin which appears to have little effect on rabbit syphilis.

T. E. OSMOND

### CHEST DISEASES

*Diseases of the Chest With Emphasis on X-ray Diagnosis* By Eli Rubin, M.D., F.A.C.P., F.C.C.P. *The Principles of Surgical Treatment* by Morris Rubin, B.A., M.D. (Pp 685, 355 illustrations with 24 plates in colour, 60s.) Philadelphia and London: W. B. Saunders Company, 1947.

The author's intention is to present the subject of chest diseases in this book so that it will serve both as a reference book for the physician and as a textbook, presumably for the post-graduate student. Throughout he especially emphasizes the radiological aspects of diagnosis. Since radiography can now be considered as an essential part of the routine investigation of intrathoracic disorders, this emphasis reflects current practice. The radiographic illustrations, of which there are many, are well reproduced—well chosen, and contribute to the understanding of the text.

The scope of the book is comprehensive. There is a useful section on the principles of surgical treatment in which the author sets forth the essentials for the physician without unnecessary reference to surgical technique. In certain passages a lack of balance is evident—for instance, in the necessarily brief discussion on the epidemiology of tuberculosis about one-quarter is on pulmonary calcification due to histoplasmosis. A useful bibliography is appended to each chapter, since the book is of American origin, it is perhaps not surprising that the references are chiefly to American publications. It may be doubted whether the 24 colour plates improve the book. These are reproductions of paintings of pathological specimens, often portrayed rather imaginatively in cross-sections of the complete thorax, together with black-and-white reproductions of corresponding radiographs and sometimes with drawings of histological appearances. They would seem more appropriate to a textbook for junior medical students or nurses than to one intended principally for graduates. On the whole, however, the author gives an adequate account of chest diseases, and we can recommend the book.

J. G. SCADDING

### GYNAECOLOGY

*Operative Gynecology* By Richard W. Te Linde, M.D. (Pp 751, 309 illustrations in black and white and 15 subjects in full colour on 9 plates, £5 10s.) London: J. B. Lippincott Company, 1947.

Te Linde's *Operative Gynecology* first published in 1946, was reprinted in January, 1947, and most British gynaecologists will be pleased that the book has been dedicated to Edward Richardson. There are two columns to a page, as in the new De Lee-Greenhill editions. Most of the illustrations are clear and on the whole satisfactory, but they are not all of the high quality of those of Karl Hryjek or of Tom Jones.

One cannot imagine Te Linde writing any textbook without introducing descriptions of pathology and it is with a certain amount of amusement that we find a whole chapter on functional bleeding without any operative descriptions whatsoever. There are also a fair number of photomicrographs. Te Linde quite correctly points out in his introduction that gynaecological surgeons should have a full knowledge of pathology. The surgeons themselves may reply equally correctly that such information can be obtained from textbooks of gynaecological pathology. Similarly, the account of gonorrhoeal disease is more clinical than operative. On the other hand the chapter on the surgical management of abortion is an excellent innovation. The author discusses the operative management of sterility too superficially. His account of vaginal operations is relatively short, and the descriptions do not compare very favourably with those of Peham, Amreich and Martius.

The book is essentially individualistic. It is informative and can be read easily. Any opinion that Te Linde expresses deserves the greatest respect, and his opinion of the merits of myomectomy is most instructive. The main criticism is that the book cannot be regarded as a condensed description of operative gynaecology. Nevertheless it will be widely read and should offer an excellent background for advanced students.

WILFRED SHAW

### MEDICAL STATISTICS

*Principles of Medical Statistics* By A. Bradford Hill, D.Sc., Ph.D. Fourth edition, revised and enlarged (Pp 252, 10s 6d.) London: The Lancet Ltd., 1948.

A book on medical statistics which passed through three editions between 1937 and 1942, was reprinted in 1945 and again in 1946, and now appears in a fourth and revised edition must have qualities which make praise from a critic superfluous and blame futile. Prof. Bradford Hill set himself the task of explaining to a clinical reader the principles of statistical reasoning without boring or puzzling him with algebraical formulae, and he succeeded so well that other medical consumers, or at least users, of statistics begged to be helped. The author has added sections of more interest to workers in social and preventive medicine than to clinicians but has done this so skilfully that the personal charm of the first edition has not been lost. The book is still primarily an introduction to arithmetic as a tool of logical reasoning which is not a bad definition of statistical method.

The careful and witty exposition of common fallacies will please and instruct many readers who have no passion for sums. It is, in the reviewer's opinion, important that such a book should be widely read by members of our profession. He can well remember the time when most medical men and many biologists despised 'mathematical' methods of handling their data—that time has passed, reverence has tended to replace contempt. From the point of view of the professional statistician this is a change for the better, but as Sir Walter Scott said all reforms bring a rateable proportion of evil. Forty years ago most doctors and medical laboratory workers were satisfied they could handle their data without any mathematical assistance. Now they are apt to think that only mathematical "experts" should handle them. It is true enough that sometimes expert help or criticism is desirable or even essential—it is not true at all that valuable statistical work even work which makes a definite addition to the methodology of statistics can be done only by a highly trained mathematician. Graunt, Farr, and Galton all made contributions to the methodology of statistics of immense value, not one of them, judged by the standard of his own age, was an expert mathematician.

If intelligent men without a natural aptitude for or special training in mathematics are frightened away from statistical work it will be bad for them and bad for statistics. Such a book as Prof. Hill's should, the reviewer thinks, give them courage, but not the spurious courage of the man who is brave because he does not know what the danger is.

MAJOR GREENWOOD

### ESTIMATION OF VITAMINS

*The Biological Standardization of the Vitamins* By Katharine H. Coward, D.Sc. Second edition (Pp 224 38 figures 16s) London: Baillière, Tindall and Cox 1947

The title of this useful book may possibly convey the impression that it is exclusively about the standards of reference which have been set up by international agreement for the various vitamins. The author certainly gives adequate attention to this important topic, but her main purpose has been to describe in detail the biological methods she has found satisfactory for estimating vitamins in foodstuffs and pharmaceutical materials, and the mathematical procedures which she has used in calculating her results. After two chapters on applying the general principles of biological methods to vitamins and on the breeding and housing of experimental animals, she describes suitable methods for estimating vitamins A, B, C, D, and E. A chapter on the independence of the vitamins follows, and then four chapters on the theory and application of statistical methods. In general she does not describe chemical and microbiological methods, but she has made an exception in briefly alluding to the antimony trichloride method for vitamin A; she also explains the estimation of this vitamin by ultra-violet spectrophotometry.

It will be clear that Dr. Coward's primary aim has been to provide a bench companion for those who wish to follow her footsteps in her own highly specialized field. The general physician particularly if he is interested in nutrition may study it with profit as an object lesson in the extreme care and patience entailed in estimating vitamins by biological methods. It has been the application of such methods over many years by pioneers such as Dr. Coward that has made possible our present detailed chemical and biochemical knowledge of the vitamins. The new edition has been brought up to date by including a chapter on vitamin E, and the chapters on the mathematical treatment of results have been extensively revised.

T. M.

Dr. E. Cunningham Dax, the author of *Modern Mental Treatment: A Handbook for Nurses* (Faber and Faber, 4s 6d), gives a simple and concise account of modern mental treatment by physical methods, yet the nurse is not allowed to forget that physical treatment, if it is to be successful, must be integrated into a wider scheme including occupational treatment and psychotherapy in its broadest sense—a scheme in which she plays no small part. One criticism may be made. One of the photographs in the appendix shows a trolley of apparatus for use in insulin treatment. It holds a strange mixture of sterile and unsterile instruments, and is at the same time inadequately equipped for a nasal interruption of coma.

### BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

## FEEDING OLYMPIC ATHLETES

Long before nutrition was the subject of serious study as a separate branch of science athletes were obsessed with the importance of their food in helping them to triumph. As Sir Adolphe Abrahams pointed out at a recent meeting of the Nutrition Society reported elsewhere in this issue (p 219), the aim of the old-time trainer was to fill his men with beef and beer and then make them work these vital ingredients "into the system". According to Schenk<sup>1</sup> the feeding arrangements for the 1936 Olympic games at Berlin followed this traditional pattern. The average daily food consumption is said to have been 7,300 calories, provided by three times as much protein, five times as much fat, and one and a half times as much carbohydrate as an ordinary man was supposed to require in those far-off days of plenty. Almost all the competitors are reported to have been heavy meat eaters, and the ingestion of large underdone steaks twice daily was not considered excessive or unusual. The allowance of milk was two pints daily, and liberal amounts of eggs, fruit, salads, sugar, honey, and white bread were consumed.

British competitors in this year's games by way of contrast are to be given one pint above the usual allowance of milk, twice the normal rations of fat and cheese, one and a half times the ration of meat, and three times the usual ration of bread. These amounts are those allowed in this country for heavy industrial workers, but they fall far short of the gargantuan feasts which must have been enjoyed in Berlin in 1936. In those days, presumably, the present weekly meat ration would have disappeared at one sitting. On purely theoretical grounds it is not easy to understand why Olympic competitors should need such enormous amounts of foods. A sprinter may do work corresponding to the output of some 400 calories in his daily training, and in a race lasting ten seconds may use up perhaps 20 to 30 calories. A long-distance runner may use up 2,000 calories in a marathon race, although he will not maintain this level of activity in his daily training. In spite of the greater daily energy output of the long-distance runner, however, his appetite will probably be considerably less than that of the sprinter. It is apparent, therefore, that food is not only needed as a fuel but also for the purpose of building up a musculature appropriate for the particular athletic event. When viewed beside the sprinter, or beside the brawny weight-lifter or heavy-weight wrestler, the long-distance runner often appears so lean as to give an impression of undernourishment.

The need to build up muscle may well explain the athlete's desire for meat even though his energy requirements might be satisfied equally well by carbohydrates.

Other possible theories are that meat may be important as a source of B vitamins, which are necessary to sustain an increased rate of carbohydrate metabolism in the muscles, or of creatine, which is also concerned in muscular contraction. Psychological factors must be borne in mind, too, for athletes who are inclined to worry and fret about their coming ordeal may be consoled and morally fortified by having plenty of good meat to eat. A craving for sugar, which is sometimes experienced by athletes after strenuous exertion, and which is also familiar to mountaineers, is probably associated with a reduced level of glucose in the blood. While most authorities agree that some Olympic competitors have huge appetites, the data reported by Schenk have been received with some scepticism. Doubts have been raised, indeed, whether members of the British teams have ever eaten quite such spectacular quantities of food.

If this year most of our Olympic athletes are subsisting on the diet which has been allowed them by the Ministry of Food, and have not greatly augmented their supplies from other sources, we may well follow their exploits not only with sporting enthusiasm but also with keen scientific interest. A generally high standard of performance on their part must make obsolete the belief that large quantities of meat provide the best foundation for athletic prowess. Dismal failure on the other hand may make us wonder whether the diet which is now consumed by our heavy manual workers is fully adequate to sustain them in their labours.

## MODERN VIEWS ON DIABETES

The modern trend in the treatment of diabetes mellitus is in the direction of standardization and simplification and the elimination of what Dr G M Wauchope, in her paper which appears elsewhere in this issue (p 191), calls "time-consuming or fussy procedures". This process of simplification has been applied both to diet and to the arrangement of insulin therapy—in the former by the use of a more generous allowance of carbohydrate and free protein and fat, and in the latter by the single injection treatment made possible by the introduction of prolonged-action insulins. In both aspects of the treatment of diabetes there is a real danger of over-simplification at the expense of good control of the disease, a tendency rendered the more dangerous by the fact that the consequences of inadequate treatment are often not at once apparent and may become so only after a period of apparently uneventful years, when there may arise irreversible complications such as retinitis and arterial and renal disease. It is important, therefore, that the carbohydrate content of the diet, however large, should be kept relatively constant and that insulin should be given in sufficient quantity and at sufficiently frequent intervals to produce a normal blood-sugar level over the period of maximum insulin action.

Wauchope describes the results obtained in the treatment of 366 ambulant diabetics with a single, morning injection of globin insulin (GI). This substance, as the author points out, resembles Hagedorn's protamine or

<sup>1</sup>*Munch med Wschr* 1936 83 1535<sup>2</sup>*Yale J Biol Med* 1945 17 705  
<sup>2</sup>*Amer J Path*, 1936 12 33

delay insulin, its effect being somewhat weaker and more prolonged than that of soluble insulin (SI) but stronger and of shorter duration than protamine zinc insulin (PZI). It is generally agreed that a single, morning injection of PZI is suitable only for relatively mild diabetics, hyperglycaemia during the day being unavoidable in more severe cases without the addition of SI. The objection to the use of GI for single, morning injections has always been that unless relatively large doses are used the hypoglycaemic action is too short to control the fasting blood sugar, and if large doses are given to overcome this difficulty there is a high incidence of hypoglycaemic reactions in the late morning or afternoon. It is difficult to understand quite why a single, morning injection of GI should be the method of choice for almost all diabetics requiring insulin, as Wauchope seems to suggest, when protamine or delay insulin, whose action she agrees is essentially similar, proved inadequate for this purpose even in the hands of Hagedorn and his co-workers. GI has now been available for five years, and it is interesting and perhaps significant that a recent survey carried out by the Diabetic Association showed that out of a total of 8,775 patients attending 42 diabetic clinics only 316, or 3.6%, were having GI alone, and 22, or 0.25%, a mixture of GI and SI.

The same tendency towards standardization and simplification is to be seen in the treatment of diabetic coma, but with an added element of acute controversy. Much of the discrepancy in results and consequent differences in opinion on the treatment of diabetic coma result from the prevalent misuse of the word coma in this connexion. In his article, which appears at page 200, Dr R. H. Micks correctly defines coma, but then departs from his definition so as to include those cases of severe ketosis which at most should be considered as pre-comatose. It is important at the outset to emphasize the fact that, in a good hospital diabetic department employing the conventional methods of treatment, the mortality rate of cases whose "mental state is one of mild, moderate, or severe confusion with marked drowsiness" but who are not in coma in the proper sense of the word is or should be negligible. It is only in cases of established coma, and particularly those of long duration, that conventional treatment properly applied sometimes fails to save the patient from death due to circulatory failure. It is important that these facts be kept in mind when considering the claims made by Root and others for the use of large doses of insulin in the first few hours of treatment. All authorities are agreed upon the importance of intravenous fluids in the treatment of coma, and there is much to be said in favour of the use of normal saline rather than glucose-saline in the early stages of treatment. The view held by Root and his followers that glucose is fatal in the early treatment of coma is less widely accepted than Micks suggests. Peters,<sup>1</sup> for example, has given good reasons for the early and continued administration of glucose-saline solution.

Far more controversial are the doses of insulin advocated by Micks. He suggests an initial dose of 100 units in conscious cases followed by a further 100 units every half-hour until obvious improvement is observed. Some authorities would hold that this dosage is contrary to accepted standards of safety and would need to be

supported by very convincing results, particularly as dosage is based on clinical improvement of a somewhat indefinite nature which should be apparent in less than fifteen minutes after giving the insulin. It is doubtful whether after so short an interval insulin given subcutaneously to a patient in diabetic coma could be shown by any ordinary chemical test to have had any action. As an initial dose in true coma 500 units is advocated, and in the absence of improvement by the end of the first hour 100 units every ten minutes until improvement begins, the chief signs of which are to be detected in mental state and hyperpnoea. Opinion may differ on the necessity of giving such heroic doses, and it is too early to pass judgment on a method of treatment which in the hands of a man of Root's experience has given good results, but a warning note must be sounded on the question of safety. Those who use such doses of insulin must remember that their hypoglycaemic action may be prolonged. It is true, as Micks points out, that death in hypoglycaemia following diabetic coma has not in the past been commonly reported, but it has occurred nevertheless, and it may occur more often in the future if this type of treatment becomes popular.

Among the irreversible complications already referred to as possible sequelae of inadequate diabetic control the one which has received particular attention in recent years in the USA is renal disease. Since Kimmelsteil and Wilson<sup>2</sup> published their original description of the intercapillary glomerular lesion in long-standing diabetics numerous articles have appeared in the American literature confirming and expanding the original findings. There can now no longer be any doubt of the existence of the lesion and its association with diabetes. It has even been said to be the commonest single pathological finding in uncomplicated cases of diabetes. The appearance, therefore, on page 194 of this issue, of a study of the renal complications in diabetes by Drs W. R. Gauld, A. L. Stalker, and A. Lyall, from Aberdeen, is particularly welcome since it is the first in our literature. The study has been made on a relatively small group of cases, but confirms the findings of earlier workers and helps to throw light on a clinical picture in which albuminuria, hypertension, oedema due to hypoproteinaemia, nitrogen retention, and retinitis are the chief features. In the past the difficulty has been to correlate clinical with pathological findings—a not uncommon problem in renal disease—but the present study indicates the existence of at least four types of renal failure in the diabetic and that the characteristic glomerular lesion, due to associated vascular changes, is incidental to and not the primary cause of the renal failure. The authors conclude on a gloomy note: prognosis is bad and treatment ineffective. While there can be no doubt about the latter, the period of two years from the onset of retinitis and oedema to death in renal or cardiac failure may be extended in some young diabetics. It is significant that the series of 26 cases reported, with the exception of 3 cases of subacute nephritis, consisted of diabetics who were between 50 and 70 years of age. The occurrence of this clinical syndrome in young persons who have had diabetes for ten or more years is becoming increasingly widely recognized and constitutes a grave problem in the treatment of the disease among the young.

## EMPIRE MEDICAL ADVISORY BUREAU

When he formally opened the Empire Medical Advisory Bureau at B M A House on July 13 Lord Addison observed that in no place could a student feel more lonely than in London. The doctor from the Dominions and the Colonies who now comes to Britain will cease to feel like a stranger in a strange land if he takes advantage of the facilities of the E M A B established by the Association and now under the direction of Dr H A Sandiford, who for the past four months has been busy equipping himself with information to turn to good account for our professional colleagues overseas. In spite of the unavoidable restrictions still in force we want medical men and women from the Commonwealth and Empire to visit Britain so that we may get to know them in person and so that they may see at first hand the various sides of British professional life. The E M A B, through Dr Sandiford, is here in the first place to welcome the doctor from the Dominions, to put him wise to our island customs, to advise him on accommodation and travel, and to smooth out the hundred-and-one difficulties facing anybody visiting this country for the first time.

Britain, we believe, has a wealth of medical knowledge and experience to offer the postgraduate student, and most of the medical visitors from overseas come here for postgraduate study, whether for the higher diplomas or for enlightenment in a special subject. The second function of the Bureau is, then, to provide the visitor with information about postgraduate facilities. In doing this it is not, of course, attempting to duplicate or interfere with the activities of postgraduate organizations. The Bureau is a marshalling yard of advice and postgraduate information.

London is fast becoming the most important medical postgraduate centre in the world. There is the Postgraduate Medical School at Hammersmith, and the British Postgraduate Medical Federation, which, under Sir Francis Fraser, has set up Institutes in special branches of medicine designed more for those pursuing advanced studies and not providing prescribed courses for higher diplomas. The Royal College of Surgeons now has facilities for systematic postgraduate courses in the various specialties. Another centre of intense postgraduate study is Edinburgh. This is to mention only a few and only some of the activities of these organizations. An important link with the Bureau's work is London House in Bloomsbury, under the Dominion Students Hall Trust, here the postgraduate enjoys many of the advantages of a student resident in a university college. Similar hostels elsewhere, for example in Edinburgh, would do much to promote a more lively feeling of fellowship with our colleagues from the Dominions and Colonies, and it is to be hoped that benefactors with a strong sense of Empire may not ignore the opportunity of attaching name and wealth to so good a cause.

The doctor overseas who wants to come to Britain to see for himself how we live and work would do well to provide and ask for information well in advance of his visit. To this end he should write to Dr H A Sandiford, Empire Medical Advisory Bureau, at B M A House. Much time and money will be saved if the intending visitor has the ground well prepared in this way. The man who wants to pursue a systematic course of study should give what facts he can about his own career and support his application with an introduction from someone qualified to speak with authority on his behalf. In the face of a high demand for postgraduate work those responsible for organizing it must naturally be satisfied that the postgraduate student may properly claim to take advantage of it. Many doctors from overseas, however, come to Britain not for systematic

courses but for instruction in certain special lines of investigation and treatment. In any case, careful inquiry before coming will enable the visitor to take the fullest advantage of what can be offered to him, and ensure that he will have at the least a warm welcome.

## SYMPATHECTOMY FOR CHRONIC LEG ULCERS

Chronic ulcers of the legs associated with insufficiency of the venous drainage are relatively common and may be crippling. The various forms of treatment which have been tried have so infrequently produced permanent cure that many have adopted the fatalistic attitude that such ulcers are incurable. Recently, however, study of the conditions which cause the persistence of the ulcers gives greater hope that a cure can be effected. The two important factors are, first, the underlying vascular defect, and, secondly, the superadded infection, usually with Gram-negative organisms of the coli or proteus groups. Streptomycin has proved most useful in dealing with the latter, and local applications have resulted in very rapid healing of ulcers of many years' duration.

The chronicity of the ulcers is mainly due to poor nutrition of the tissues, partly from the sluggish blood flow and partly from the oedema of lymphatic stasis. The ulcers associated with primary varicose veins with incompetent valves usually respond rapidly to a properly conceived and executed ligation operation, and this should be the first line of treatment in such cases. The majority of chronic ulcers are, however, associated with impairment of the drainage in the deep veins, and in these improvement in the circulation can be achieved only by other methods.

Recently lumbar sympathectomy has been undertaken with the object of improving the circulation in the limb. The results claimed have been divergent, some writers, such as Allen, Barker, and Hines,<sup>1</sup> reporting that the operation has no effect on the healing of the ulcers, and others finding marked improvement and rapid healing as the outcome. Mr J Borrie and Mr E Vernon Barling, for example, report in this issue of the *Journal* four cases of chronic ulcer which healed rapidly after the operation and only one has subsequently broken down. There must be some explanation for these conflicting views, and it seems to lie in the type of case selected for operation. Sympathectomy is by no means always successful, occasionally unilateral sympathectomy performed on patients with ulcers on both legs has produced no faster rate of healing or more permanent cure than was observed on the unoperated side. In these cases the skin round the ulcer is pigmented rather than cyanosed, and the ulcer base is callous and relatively avascular. It must be that tissue fibrosis and local endarteritis have progressed to cause severe local organic ischaemia which cannot be relieved by the removal of sympathetic tone. Again, the foot is frequently warm in such cases, an indication that no excessive sympathetic activity is present. Sympathectomy is more likely to be successful when there is cyanosis rather than avascularity in the region of the ulcer, and the foot is often colder than its neighbour. It is only by careful differentiation of these types, combined with the response to paravertebral sympathetic block, that the patients likely to benefit from sympathectomy can be selected. In this connexion a good response to the block is best judged by the improvement in the colour of the ulcer and surrounding skin rather than by the change in the temperature of the foot. In all cases local support by some form of elastic bandage is of the greatest importance in maintaining improvement and preventing relapse.

Too many patients are still treated with varied local applications and are seen by the surgeon only after years of such therapy. A more widespread appreciation of the benefits which surgery can offer in many of these cases would result in a great saving of suffering and time. There is no doubt that treatment which combines improvement in the local circulation and defeat of the persistent infection enables a more optimistic view to be taken of this condition than in the past.

### THE DEATHS OF DOCTORS

In assessing a fair remuneration for general practitioners the Spens Committee pointed out<sup>1</sup> that the strain of medical practice shortened the expectation of life of doctors, who have a mortality rate 34% above Civil Servants and 26% above professional engineers. Unfortunately, owing to the war, no up-to-date occupational mortality statistics are available for this country, but the gap has been partly filled by recent American reports on the longevity of physicians.<sup>2,3</sup> A comparison between the mortality experience of doctors and the remainder of the male population over the age of 25 shows that, although the main causes of death among doctors are not appreciably different from those among the white male population as a whole, the relative importance of the individual causes varies considerably between the two groups. Thus, although the overall death rate for doctors in the U.S. is little higher than that for the general male population, the advantage held by doctors under 45 is largely outweighed by their heavy death rate at later ages. This divergence is due to the differential mortality from specific causes of death.

The mortality ratios, which express the proportion of deaths actually observed among doctors to the number to be expected at the rates prevailing in the general male population, show that the former have an unduly heavy death rate from leukaemia (M.R. 1.75), biliary calculi and gall-bladder disease (1.45), cerebral haemorrhage (1.2) diseases of the heart and coronary arteries (1.18), and arteriosclerosis (1.16). On the other hand doctors have a death rate below general expectation from automobile accidents (M.R. 0.89), cancer (0.81), appendicitis (0.77), hernia and intestinal obstruction (0.75), nephritis (0.73), peptic ulcer (0.62), diseases of the prostate (0.54), tuberculosis (0.45), and syphilis (0.34). Clearly this latter group of causes of deaths comprises just those diseases whose fatality rates can be reduced by early diagnosis and rapid and effective treatment. Most of the causes of unduly heavy mortality among doctors, on the other hand, are those believed to result from the stress of a harassing existence which weighs most heavily on men past their physical prime. Thus, although the expectation of life of a young doctor of 25 is slightly higher than is usual in the population—43.5 instead of 43.3 years—this advantage is lost by middle age, when, at the age of 55, a doctor has an expectation of life of 17.9 years, six months less than the general expectation.

These findings have two important implications. The first is that, despite the disregard which many doctors notoriously have for their own health, their favoured position, both professionally and socially, does result in a lessened mortality from diseases amenable to detection and treatment. Their cancer experience, which is particularly good for neoplastic disease of the digestive tract, is

a powerful argument in support of the campaign for early recognition and treatment of cancer. Conversely, their high death rate from cardiovascular diseases cannot be entirely explained by better diagnosis, though this, rather than any specific occupational hazard such as x rays, may be the reason for the exceptional mortality from leukaemia, which is shared by men of social class I in this country. There is, then, a need for special study of the occupational and constitutional background of those "stress diseases" which so often cut down men at the peak of their maturity and usefulness, both in our own profession and in others.

### LIBERATION OF HISTAMINE BY CURARE

In 1939 Anrep and his colleagues<sup>1</sup> observed that the injection of curare into an artery supplying the muscles of a dog's leg set free in the blood a substance which behaved like histamine. This observation, which at the time aroused only academic interest, has now gained practical significance because of various unusual effects which have been described in patients to whom curare has been given either as "intocostin" or as *d*-tubocurarine chloride. Thus occasionally the intravenous injection of curare causes a transient fall of blood pressure accompanied by a feeling of warmth, giddiness, and headache, exceptionally the fall of blood pressure has been severe and accompanied by haemoconcentration.

Grob, Lilienthal, and Harvey,<sup>2</sup> at Johns Hopkins, have recently investigated the action of curare on the cardiovascular system in man, using the methods they introduced for the study of the action of neostigmine ("prostigmin") in myasthenia gravis. They injected curare into the brachial artery below a pneumatic cuff which was inflated to 100 mm for two minutes after the injection. They found that the injection of an amount of curare equivalent to about 7 mg of *d*-tubocurarine chloride produced an effect very like that of 0.25 mg of histamine base. The curare caused a loss of power which was not produced by histamine, but when the cuff was released the forearm became intensely hyperaemic and engorged. Numerous areas of purple discoloration like ecchymoses appeared. They vanished in the next 30 minutes. As they faded the arm swelled with a firm oedema, broad weals appeared, which often itched. The swelling disappeared in 16–36 hours according to the dose given. These changes occurred with curare and with histamine. The effect of injecting curare into the skin was also studied. Again the resemblance to the action of histamine was complete, the triple response described by Lewis being observed in all its stages. Intra-arterial injection of curare also caused a rise in acid secretion in the stomach.

Final confirmation of the view that curare liberated histamine was obtained when Harvey and his colleagues were also able to show that these effects of curare were greatly diminished or abolished by antihistamine substances such as "pyribenzamine" or "benadryl". Thus when 200 mg of pyribenzamine was taken by mouth 30 minutes before the intra-arterial injection of curare the local swelling and the local and general skin temperature changes did not appear. On the other hand, neither atropine nor neostigmine modified the vascular effects of the drug. It should be emphasized that these vascular effects were not observed when curare was injected intravenously, they followed only intra-arterial injection. Occasionally in susceptible subjects, however, they may occur in minor form after intravenous injection, and can then be counteracted by the injection of a suitable antihistamine drug.

## DERMATOSIS IN THE PAINT INDUSTRY

In view of the great variety of constituents of paint and their skin-irritant properties it is scarcely surprising that workers who handle paints suffer considerably from dermatosis. It appears from a recent investigation<sup>1</sup> in Finland that of all the ingredients—oils, resins and other binders, inorganic pigments, organic dyes and pigments, and organic solvents—the organic solvents are the chief offenders. These include turpentine, aliphatic and aromatic hydrocarbons, alcohols, esters, ethers, and ketones. The responsibility for an incidence of 10.7% of occupational dermatosis among paint workers in Finland rests very largely on the greatly increased use during the war of sulphate and kiln turpentines, with their content of high boiling-point fractions (carene, limonene, dipentene). The aliphatic and some of the aromatic hydrocarbons, dye solutions, and whitewash also produced a few cases of irritation, but lead, its salts, and white lead not a single case. It was found that the charwomen and cleaners of paint pots were most frequently affected, workers in the paint factories suffered less severely, and the actual painters, polishers, and sprayers least of all.

The dermatosis is generally of two distinct varieties—toxic dermatitis and allergic eczema, the latter is distinguished by the slow development of sensitization, short latent period, long duration, and greater severity. Patch tests are valuable in confirming the diagnosis of allergic dermatitis, but are not always conclusive, being positive in only 18% of cases of occupational dermatosis. The final diagnosis must therefore be made on the course and symptoms of the disorder, the occurrence of attacks following exposure to a known toxic agent and improvement after cessation being of course very significant points. Hereditary and constitutional factors (such as a blonde complexion and a seborrhoeic skin) appear to play less part in predisposition to allergic dermatitis than has hitherto been generally believed but women do tend to show greater susceptibility than men.

The disability resulting from dermatosis among paint workers is considerable, not only because of the duration of the actual disorder—usually about six months in allergic eczema—but because relapse after return to work often necessitates a complete change of occupation. Among the preventive measures recommended, prohibition of the use of solvents for cleansing the skin (a widespread habit among all workers who use contaminating materials) needs special emphasis. The use of non-irritating detergents for cleansing should be encouraged, and protective ointments are of some value, but the most important factor is the restriction of those ingredients, particularly the irritating turpentines, which have been found to possess toxic properties.

## LISTER MEDAL

The Lister Medal for 1948, which is awarded in recognition of distinguished contributions to surgical science, has been granted to Professor Geoffrey Jefferson, CBE, FRCP, FRCS, FRS, Professor of Neurosurgery in the University of Manchester, in recognition of his contributions to "knowledge of the functions and structure of the nervous system, made as a philosophical biologist, practising neurosurgery." Professor Jefferson will deliver the Lister Memorial Lecture in London in June, 1949, under the auspices of the Royal College of Surgeons of England. This is the ninth occasion of the award, which is made by a committee representative of the Royal Society, the Royal College of Surgeons of England, the Royal College of Surgeons in Ireland, the University of Edinburgh and the University of Glasgow.

## FATTY LIVER DISEASE IN INFANTS

The high incidence of hepatic disease among infants in tropical and subtropical areas has again been discussed. With the exception of so-called infantile biliary cirrhosis in India the disease is usually associated with poverty and malnutrition. Waterlow<sup>1</sup> has recently reported that in the West Indies the disease occurs almost entirely in infants under two years old, in most cases the symptoms started shortly after weaning. They included vomiting and oedema, and the liver was enlarged. Necropsy and biopsy showed that the enlargement was the result of severe fatty infiltration. Symptoms of associated vitamin deficiencies, which were a conspicuous feature of the cases reported from Africa,<sup>2,3,4</sup> were usually insignificant in Waterlow's cases, and certainly none had pellagra.

Recent experimental work on animals has clearly shown that severe fatty infiltration of the liver may result not only from exposure to toxic substances but from dietary deficiency. The dietary factors concerned in the prevention of fatty infiltration are termed lipotropic, and the two best established are choline and methionine, the former a member of the B vitamin complex, the latter an amino-acid widely distributed in proteins of high biological value. There are also other factors associated with fat metabolism. Inositol, pyridoxin, tyrosine, and some oestrogens have lipotropic activity, while excess of biotin, cystine, or nicotinic acid has the opposite effect. Possibly many other unknown factors affect the fat content of the liver, although choline and methionine are of great importance in the rat for their lipotropic activity, it does not follow that they are the principal lipotropic agents in man. The disappointing results obtained by Waterlow when he used these two substances in a very small series of human cases are therefore not surprising and are in accordance with the African workers' experience. However, the striking improvement in several cases that followed ingestion of moderate amounts of milk helps to confirm the generally held opinion that the condition is one of nutritional deficiency. But, as Waterlow points out, since this so-called "fatty liver disease" does not occur in cases of pure starvation it is better regarded as a result of nutritional imbalance rather than one of pure deficiency. The most obvious defect in the dietary of the affected infants is an absolute inadequacy of protein associated with a relative excess of carbohydrate. From the work of Best<sup>5</sup> and McHenry<sup>6</sup> it seems probable that the carbohydrate is the source of the liver fat, while deficiency of protein is responsible for the lack of lipotropic activity.

Since the disease does not appear before weaning and is apparently remediable by adding milk to the diet, the solution of these important problems lies in the production of more milk or milk substitutes. Unfortunately food yeast, despite its high lipotropic activity in the rat,<sup>7</sup> has proved to be therapeutically ineffective both in Africa and in the West Indies, and the work of the Gillmans suggests that it is not entirely without danger as a supplement in malnourished individuals.

Dr George Brock Chisholm, of Canada, who was Executive Secretary of the Interim Commission of the World Health Organization, was appointed Director-General of the Organization at the meeting of the World Health Assembly now being held at Geneva.

## TREATMENT OF ANXIETY STATES IN GENERAL PRACTICE

BY

C A H WATTS, MB, BS, DRCOG

Recent correspondence in the Press has shown that some practitioners are alarmed and dismayed at the incidence of neurosis in general practice. The figures given vary from 14% to 50% of all patients seen. It is obvious that to many doctors neurotics are the bugbear of general practice, and that means that a substantial proportion of their patients receive grossly inadequate treatment. Anxiety gives rise to more suffering and distress than any other aetiological agent of disease. Its treatment is not as complicated as many imagine, and this paper is an attempt to describe one method by which the problem can be tackled in general practice.

The vast majority of neuroses seen in my practice can be dealt with at the surgery. Only a small proportion of patients need to be put off work for a week or two. Most neurotics can be treated while continuing at work. This is not only better for the community as a whole but it is also better for the patient. It underlines the fact that he is not physically ill. Thus the general practitioner's surgery is in many ways an ideal treatment centre for neuroses.

### First Interview

The patient is encouraged to expound all his symptoms. He is encouraged to talk and get everything off his chest. When he can think of no more symptoms I question him about each part of his body to make sure he has missed nothing from his history. Details of previous ill-health are recorded, as well as the family medical history. I ask for the earliest memory the patient can give me. The average person remembers back to about five years. The reason for this question will be seen later. I find out what kind of scholar the patient was as a child, and a detailed history of employment is taken. Habits are recorded, including smoking, drinking, sociability, pastimes, and hobbies. Details of the marriage are taken if these are applicable. If the patient is unmarried romantic situations are discussed. I do not make notes on sexual matters, as I feel it may embarrass the patient. Any points of note can be added later. To determine attitudes to parents I ask such questions as, "When a child of 12 to which parent would you have gone for extra pocket money, advice, and so on?" Most patients name either one or other parent. Very few say they have no preference. Such a bias is useful evidence, and as Case 206 shows, such feelings can play a part in a neurosis.

To exclude organic illness a complete physical examination follows the history-taking. The above preliminaries sound lengthy, but one picks up speed with practice, and I can usually clear my way for psychotherapy in one or two sessions. If the case is a neurosis the patient is told that his symptoms are due to what is popularly known as "nerves." I stress the importance of both speaking the same language and understanding each other. I explain that the symptoms are due to anxiety, and I point out that worry can produce pain as severe as any toothache. I make sure he doesn't go away with the impression that I think either that there is nothing wrong or that the pain is imaginary.

### Psychotherapy

The next session opens with a summary of my previous remarks. If the patient needs convincing that the mind can upset bodily function I ask him what happens if he goes to church without a pocket handkerchief. This usually produces the correct answer, and I point out that just as worry can upset the nose so it can upset the rhythm of the heart, breathing or any other bodily function. I stress the fact that although worry can cause symptoms, that does not mean the body is diseased. It is sometimes profitable to explain to the patient how fear works, and to point out that anxiety is the same reaction, only it is prolonged in time. Palpitations, dyspnoea, sweating, and an empty feeling in the middle can all be explained in this way. The condition is liable to form a vicious circle. Anxiety causes symptoms and the symptoms increase the anxiety. Reassurance

helps to break this vicious circle for a time, but by itself it is usually insufficient. It is necessary to go deeper and to work out the mechanism of the neurosis as well. My methods may be summarized as follows:

1 *Direct Approach*—This means a correlation of symptoms and circumstances. Case 24, described below, illustrates this method.

2 *What Useful Purpose does the Neurosis Serve?*—All neuroses are motivated at a subconscious level. Some useful purpose is served even if the bargain as a whole is a bad one.

3 *What Emotions does the Neurosis Express?*—A case of effort syndrome may be the result of a broken romance. There is such a thing as a broken heart.

4 *Dream Interpretation*

5 *Free Association*

One, two, or more of the above approaches may be used in an attempt to discover the patient's real problem and to make him face up to it.

### 1 The Direct Approach

Sometimes the patient frankly admits he has problems, and these can be freely discussed. More frequently, however, he will affirm that he has no worries. I reply that a person can worry about something of which he is unaware. Here it is often necessary to describe the subconscious mind. I remind the patient of the iceberg, pointing out that whereas only one ninth sticks out of the water, eight-ninths is submerged and hidden from view. The same applies to the mind. I describe the subconscious as the hidden part. It is in fact the storehouse of forgotten memories. Here the date of the earliest memory comes in useful. Most people readily appreciate that the early life and training of a child are of great importance and yet these vital years are largely forgotten. The memories are buried in the subconscious mind, and from there are able to influence the individual.

*Case 394*—This patient, a woman aged 25, was adopted at the age of 2. She had no conscious memories of her first two years of life nor of the town H in which she was reared. At 14 she was told by her foster mother that she had been adopted. She told her mother that she knew already, although she was certain no one had mentioned it. Clearly she had never completely forgotten. The name of the town H always filled her with forebodings. Once when a van from H stopped at the door she ran upstairs and locked herself in her room for four hours. She was 7 years old at the time. All this fear of H went when she knew about the adoption. For the first time she realized she was secure and could not be taken back to H and to her first home, which she had long forgotten.

A case such as this may be quoted to illustrate subconscious memories. After some such digression I ask the patient to tell me when the symptoms first started. We go over details not of the feelings but of the background. Something in the circumstances has upset the patient. He is not facing up to reality, and his symptoms are a useful red-herring across the trail. In discussing the first attack one often comes across some clue or something worth opening up.

*Case 36*—This man of 24 was suffering from effort syndrome. His first attack came on in Switzerland, where he was awaiting repatriation as an escaped prisoner of war. He remembered that he was then writing to his aunt, but as the letter had been written some eighteen months prior to my interview he had no idea of its contents. I told him that something in his letter had upset him and that if it was important enough to upset him it could not really have been forgotten. I told him that if we left the subject and talked of other things the memory might return.

"What do you think of your aunt?" I asked him. "I'm very fond of her," was his immediate reply. We discussed the old lady. She was his foster-mother, but, being a maiden lady, she was called aunt. She had been kindness itself to him, but he was anxious to break away and stand on his own feet. After half an hour of discussion I repeated my question, "What do you think of your aunt?" "It's a mixture of gratitude and indifference," was his reply. In his first answer he had given his conscious feelings or the orthodox reply which was expected of him. His real feelings had to be stimulated before they were obvious, especially to himself. We broke off the session at this point, but as he reached the door he remarked, "I know now what was in that letter." He told me he was replying to a request from his aunt. She had made him the generous offer of a farm which she wanted him to take over. If he accepted the offer he would lose the independence for which he was striving. It was not easy to word a letter refusing the offer without hurting her feelings and appearing ungrateful. Syncope came as a

temporary respite from his struggle. The mechanism is often clear to the therapist before the patient has any idea of what it is all about, but it is better for the patient to reason out his own problems. Time will not always allow this process, which is necessarily slow, so that once I feel the patient has a grasp of elementary psychology I am often prepared to elaborate the case as I see it. If he can intellectually accept my suggestions he usually improves, but it is surprising how quickly the mechanism is forgotten from one session to another. Constant repetition and going over old ground is usually necessary.

If discussions as illustrated above do not bring the problem to light there are the other lines of approach.

## 2 What Useful Purpose does the Neurosis Serve?

This method is well depicted in the following case.

*Case 208*—A woman aged 42 had called me in because her only child, aged 4, had developed mannerisms and was unduly afraid of cows. I asked her mother to come and see me at the surgery, and it was soon obvious that she herself had a quite severe anxiety state. She complained of pains in her chest and shortness of breath. She had given up cycling and had cut down all her activities. She was convinced it was only a matter of time before she dropped down dead. So sure was she of this that she always carried her identity card so that her body would be recognized. She even had a farewell letter to her husband telling him how to carry on. Such precautions are a measure of how bad she felt. To summarize the case, which in all took four sessions, she had a pronounced "Atalanta complex" and was markedly fixated to her father, who had died two years previously from heart disease. As is often the case in neuroses, his illness served as a pattern for her symptoms. So great was her fixation that she was courted for nine years before she would consent to marry at 36. Attracted by her father, she was strongly antagonistic to her invalid mother, who lived at the other side of the town. She visited her mother thrice weekly, but it was an irksome duty and gave her no pleasure. Consciously she strove to be dutiful, subconsciously she hated her mother and resented the attention she had to pay her. This is roughly what must have happened. When she felt tired one day she decided she was not fit enough to make the journey. 'I would go if I felt better,' was her feeling, and so she stayed at home. The purpose of the neurosis is clear. She gave up cycling, and if she had to use a taxi the visits could be cut down to once a month. As T. A. Ross (1937) put it, a neurosis is always a bad bargain in the end. Her feelings excused her certain duties towards her mother, but in the end they made life almost unbearable for the patient herself. Once all this conflict had been clarified at a conscious level the patient felt much better. After the third session she announced herself as well. She could run upstairs and swill the yard in a way she had not done for months. All her fears had left her, and, what is more, her little girl had recovered too. I don't know much about child psychology, but treatment of the parent often brings about recovery.

## 3 What Emotion is Expressed by the Neuroses?

*Case 24*—This young soldier was referred to me for persistent vomiting. No physical cause for his complaint could be found. He had escaped from a P.O.W. cage in Italy and for a year had lived the life of a bandit. The day after he had reached the British lines—and safety—he started vomiting. I could find no reason at first, so I flung out at him, "What does vomiting express?" He could not see my point, so I told him it could be a sign of disgust. I related the story of an Englishman who, having enjoyed a French dish of frogs' legs, was sick when he heard of what he had eaten. My patient opened up at once. Talking of disgust, he said he had never been so shocked in his life as when he was rescued. The Fascist mayor of an Italian village had entertained him with the object of trying to make a good impression. When my patient heard English voices outside he went out and greeted a tank commander. They smoked a cigarette and arranged a rendezvous, as the tank had to complete a patrol before picking him up. When the tank moved on he returned to the house to find that the mayor and his wife and family had all been butchered by patriots. Their brains bespattered the walls and their bellies were ripped up. He said he had never seen such a disgusting sight in his life. The next day he started vomiting.

The correlation of symptoms and circumstances was very instructive in this case. He had been a bilious child, and with some hesitation he produced this story. His father had died when he was 5. His mother took to drink, but he didn't realize this until he was about 7. He found her sitting at the table so ataxic that she could not put her mouth with her spoon as she ate. He told me he would never forget the feeling of dismay and disgust that swept over him. So far as he could recollect his bilious bouts came on after this incident, and it looked as if they served a very useful purpose in forcing his mother's attention on him from time to time. Later, as a clerk in an insurance firm, he frequently lost work

owing to his attacks. He did not like the work, and he felt that his talents were being exploited. When the director of his firm visited his office he sought an interview with him. He evidently made a good impression, as he became the private secretary to this man, his salary was raised, and he had no more attacks of vomiting. He had never correlated his symptoms with his environment. The comparison showed how vomiting on each occasion had expressed disgust.

While on week-end leave this man had an unpleasant experience. He was to visit an uncle, but when he got there he found his host had committed suicide and the family were in a turmoil. I asked him if he had been sick. 'I felt nauseated,' he said, but after our talks I felt I should be able to control myself, and I never actually vomited."

## 4 Dream Interpretation

Freud described dreams as the highway to the subconscious. In a paper such as this it is impossible to go fully into the subject, but I find it useful on occasion to explain the rudiments to my patient. Dreams all have a meaning, sometimes it is obvious, but more often it is obscure. Dreams are like cartoons. At face value the picture is ridiculous, but there is a hidden meaning behind it. Frequently there is a wish fulfilment. The hungry P.O.W. would dream of Christmas dinner at home, and so on. Dalbiez's (1941) book gives some very useful chapters on Freud's teaching about dreams, and dreams by their revelations can often considerably shorten treatment. I usually ask patients to write down any dreams they have between the sessions, as the treatment itself often stirs things up and useful information emerges during sleep.

A woman came to see me about a phobia which had troubled her since she was 13. We could find no trigger incident to put the neurosis in motion at that age. I told her I was confident that we would find something, and I asked her to remember her dreams. The next session she came back and said she had dreamed someone had left a brown-paper parcel on the doorstep. She awoke and found herself in an awful state. I know now what upset me at 13," she said. Then she proceeded to describe how one day when she came home from school she had found a brown paper parcel on the kitchen table. She was curious and looked inside. It contained soiled linen and a placenta. She did not know what it was, but she felt guilty about the whole affair and associated it correctly with the birth of her youngest brother. Soon afterwards her periods started and the same feelings of guilt assailed her in spite of her mother's meagre assurance that it was a normal event. When I questioned her about these memories she affirmed that so far as she could remember, she had never given the matter thought since her marriage seven years previously.

The most ordinary dream may have a profound significance. Case 394 reported that she had dreamed she was placing a wreath on the grave of a brother who had been killed in a gravel pit accident six years previously. My first impression was that this dream was a compliment to that brother whom she fondly remembered in her dreams. I heard her sob and found her in floods of tears. Such an emotional outburst is always most satisfying, as one can be sure one is hot on the trail of something important. In a few minutes the problem was clear. When she could speak she told me her father-in-law owned the gravel pit, and the two families were at loggerheads because of this fatal accident. She could not discuss the matter with anyone—even her husband.

After this session, without any prompting from me, she told her husband all about it. He laughed at her and reassured her, and when I saw her again her troubles were at an end.

## 5 Free Association

This is sometimes very useful, but I do not often use it. The patient is shown how to relax on a couch and is told to repeat whatever comes into his mind, however strange or out of place it may seem. I must point out that it takes practice on the part of both patient and doctor to achieve proper relaxation. This method is useful in long-term cases or when a resistance is holding up progress, but I do not have many long-term cases. Hypnosis and narco-analysis I have never used in general practice.

*Short Cases*—If one is on the look-out for neuroses, and examines the patient as a whole in his environment, one can frequently give considerable help with very little trouble or expenditure of time.

*Case 357*—This girl, aged 17, when seen was complaining of loss of appetite and feeling sick. She looked a picture of health after

her seaside holiday While she was getting into bed upstairs I questioned her mother about her, and learned she was about to go to college She was leaving home for the first time in her life She had an over-protective mother, and I knew the girl would feel the wrench I discussed these possibilities with the mother and then went to examine the patient Nothing abnormal was found and I put forward my views to the girl I felt that the queer feeling in her middle was due to the apprehension about leaving home When I got downstairs the mother told me she was sure I was right, as the same thing had happened when the girl started school A follow-up some months later showed that the feelings had cleared after a few days at college She herself was well satisfied with my diagnosis In all, this case took about half an hour of my time It required no medicine and no further attention

**Chronic Cases**—Some patients improve up to a point, but can get no further, these require an occasional maintenance dose of psychotherapy This is truly tiresome and often disheartening, but in my view it is far more honest than putting off the neurotic with a bottle of medicine

**Case 142**—This patient was a woman of 40 Her troubles began at 16 when spinal disease was diagnosed and she was put on her back for three months Since that time she has always had a "weak back," although no G.P. or specialist has been able to explain why From the psychological point of view she had enough to break anyone's back She was an intelligent and very capable person, but at 14 all hope of advancement along her own lines went when she was drawn into the family business because of her mother's illness The family were thrifty and hard-working to a degree of absurdity Work and money making were the only things that mattered Social life was frowned on, smoking and alcohol were forbidden At 40 her mother still referred to her as a young girl and treated her as such After a few sessions there was a vast outpouring of hatred against her mother with floods of tears After that she felt better but never completely well How can she get well under such impossible circumstances? Every six weeks I see her for a painful three-quarters of an hour, during which time she pours out her woes and her resentment against the family Until her parents die she is in a hopeless trap She has not the training, resources, or the courage to go elsewhere, but she can relieve her feelings to me whenever she likes and on the whole she is better She at least puts the blame where it rightly belongs and does not waste my time talking about her back

#### Other Conditions

I have referred in a previous article (Watts, 1947) to the "feel" of functional cases The typical neurotic willingly co-operates in treatment and takes a real interest in what is going on If the patient is constantly difficult and lacks the spirit of co-operation the condition is probably not a neurosis but one of the following

- (i) Psychotic—chiefly endogenous depression This condition is quite as common as the anxiety state
- (ii) Mental defect
- (iii) Psychopathic personality
- (iv) When the neurosis is too profitable to abandon It is almost impossible to cure a neurotic on a pension, where a cure of the complaint spells financial loss

**Mentally Retarded**—While deeper forms of psychotherapy are impossible with the mentally retarded, sympathetic handling can do a great deal to jolly them along One of my best cases was that of a girl of this type She had not worked for ten years because she felt too ill By winning her confidence and with persuasion I made her accept my idea that she felt ill because she did not work and that work itself would make her feel better, not worse After four months of patient prodding she took the plunge, and in ten months has missed only two weeks of work

#### Comment

**Drug Treatment**—Drugs play a useful part in treatment In an article of this type it is impossible to go into details I fully endorse the views of Sargant and Slater (1948), and the rationale of drug therapy is explained fully in their monograph The point I stress with patients is that drugs will not cure a neurosis Recovery will only take place with successful psychological treatment I explain the situation to them as follows "If you came to me with a broken leg you would not be satisfied if I handed you a crutch and told you to manage on that Your objective would be to get the fracture set and the leg made useful again Drugs to a neurotic are a useful crutch, but no

more They are only a temporary measure, and in no way replace psychotherapy, which aims at complete recovery

**Results**—In a series of 70 consecutive cases 35.7% recovered, 34% were improved, 18.6% were not helped at all, and the remaining 11.6% have not been traced

#### Conclusions

In general practice it is necessary to view the patient as whole in his family and social environment I try to locate the stresses and strains he is up against, and endeavour to make him appreciate his real problems The neurotic tends to turn his back on difficulties and complains about his symptoms I largely ignore his symptoms and get him to face up to his problems Above all, I try to make him use his powers of reason in the matter The intelligence of man has made him more anxiety-prone than other animals, but fortunately intelligence also points the road to recovery

#### Summary

The need for psychotherapy in general practice is stressed The family doctor's consulting room should see a solution to most neuroses

Methods used by the author are outlined and illustrated by cases and samples of his "patter"

I would like to express my appreciation to Dr J. D. W. Pearce for his encouragement in the writing of this paper, and to Dr Alice Cox, who taught me psychiatry

## INTERNATIONAL LEPROSY ASSOCIATION CONGRESS IN CUBA

The Fifth International Leprosy Congress was held in Havana, Cuba, from April 3 to 11 The previous international congresses were held in Berlin (1898), Bergen (1909), Strassbourg (1923) and Cairo (1938) At the Cairo meeting it was decided to hold quinquennial congresses, and the next was to have been in Paris in 1943 Unfortunately this was prevented by the war

The initiative in calling this Congress, as also the Cairo Congress, was taken by the International Leprosy Association, a body formed in 1931 at a meeting of leprologists at Manila called by the American Leprosy Foundation Two of the chief functions of this association are the publication of the *International Journal of Leprosy*, which is produced in America with the assistance of the Leonard Wood Memorial, and the arrangement of periodical congresses Its office and secretary-treasurer have from the beginning been furnished by the British Empire Leprosy Relief Association in London In 1946 the Association accepted an invitation from Cuba to hold the fifth congress in Havana and the Cuban Government invited all countries to send delegates Two hundred and twenty-nine delegates, including 74 from Cuba itself, gathered from 36 different countries Important countries not represented were Russia, Japan, Australia, Pakistan, and Indonesia By far the largest delegations were from the Latin countries Spain 12, Portugal 4, Brazil 28, Mexico 16, and Argentina 15 There were 31 delegates from the U.S.A., but only 14 from the British Commonwealth In Cuba itself leprosy is a serious problem, and carefully planned steps are being taken to bring about control

While the International Leprosy Association was chiefly responsible for arranging the scientific side of the Congress, the Cuban Government made all the local arrangements The Congress met in a large school building, with dormitory arrangements for 60 delegates in the top story and a restaurant on the ground floor supplying food at or below cost price, while on the first floor there were offices and committee rooms, a post office, and exhibitions, together with a large auditorium with seats for 400 and interpreters for the four official languages—English, French, Spanish, and Portuguese Delegates were supplied with earphones so that each could hear the speakers in his own native tongue

The organization of an international congress on democratic lines is not easy. Apart from the language difficulty, all the preliminary arrangements have to be made by post, and the final plans must be compressed into the last few hours when the council members have arrived from the four quarters of the globe. In each of the seven working days of the Congress much time was occupied by social engagements. The plenary sessions for the reading and discussion of papers were concentrated into some 23 hours, about 100 papers being presented. The programme was divided into therapeutics, classification, research (including pathology, bacteriology, blood chemistry, serology, and immunology), epidemiology (including distribution and control), and sociology. Four committees were appointed (therapeutics, classification, epidemiology, and sociology) to discuss controversial questions and to frame resolutions for submission to the final plenary session.

### Classification and Therapy

The chief interest centred round classification and therapeutics. Leprosy shows itself in protean forms, but the majority of cases can be divided into two types: (1) the mild form (tuberculoid), in which the patient has a comparatively high resistance to the infection, the nerves are more affected, the bacilli are few, and therefore the danger of spreading infection is nil or slight; (2) the severe form (lepromatous) in patients with low resistance and enormous numbers of bacilli, who are therefore responsible for disseminating the disease. The difficulty arises in classifying a minority of cases which do not conform to these two types. Should they be divided on a clinical, histological, or immunological basis? The whole matter is still obscure and much further research remains to be done. Meanwhile it was agreed to divide cases into two main types: lepromatous (malignant or *gravis*), with 'L' for its symbol, and tuberculoid (benign or *mitis*), with 'T' for its symbol. In addition an 'indeterminate group' was recognized of cases which are "less stable and less certain with respect to evolution" their symbol being 'I'. The importance of the lepromin test was stressed in determining classification, as showing the degree of resistance to the bacillus.

The other subject which aroused special interest was sulphone treatment. These derivatives of diaminodiphenyl sulphone ("promin", "diasone" and "sulphetrone"), at first received with suspicion as another of the periodic leprosy "cures", are now universally recognized as a forward step in treatment and possibly in control. The most striking clinical results are in advanced, ulcerating lepromatous cases with the nose obstructed and vision vanishing. But the real criterion from both the therapeutic and the control aspect is the diminution and disappearance of bacilli. In a large proportion of cases, however, disappearance is long delayed, and a few cases appear to be altogether recalcitrant.

The general opinion was that chaulmoogra oil, though still considered useful, is gradually taking a secondary place in all but the earlier cases of the mild type, but that sulphone therapy might be reinforced by the simultaneous use of chaulmoogra and other drugs. On the whole however, it was generally agreed that the prospect of recovery from leprosy is much brighter to-day than it was a few years ago, though a vast amount of research remains to be done by both chemists and clinicians.

A discussion took place on the use of certain terms such as 'leper' and 'leprosy' which, because of their popular derogatory significance may be offensive to patients. It was decided that the word 'leper' should be avoided as much as possible, but that it was more important to educate the public regarding the true nature of leprosy and the need for sympathy with its unfortunate victims.

The generosity of the Government of Cuba, the energetic work of the local committee and the hospitality of the Cuban citizens left nothing to be desired on the social side of the Congress. Something too, was accomplished on the scientific side though not as much as was desired or as some delegates had expected. But the main object of a Congress is after all what its name implies, 'getting together' and from that point of view this meeting was well planned and of considerable value. The next International Leprosy Congress has been fixed for 1953, and will be held in Madrid.

## MEDICINE AND PHYSICS CONGRESS AT BRUSSELS

[FROM A CORRESPONDENT]

The formal opening of the Twenty second Medical Congress took place at the Palais des Academies in Brussels on June 13. The Belgian Minister of Public Health presided, supported by the Rector of the Free University of Brussels and other dignitaries, and welcomed the many delegates from Great Britain, Canada, Czechoslovakia, France, Italy, the Netherlands, U.S.A. and Switzerland. On the occasion of this congress the Belgian Society of Physiotherapists, under its president Professor J. Michez, took the opportunity of calling together the first post-war international meeting on 'medical electronics'. The purpose of this meeting was to re-establish a body existing before the war known as the "International Association of Physiotherapy". It soon became apparent that the term "medical electronics" was not wide enough to embrace all the interests which the proposed association would serve. Dr P. Bauwens proposed the name 'The International Association of Physical Medicine,' and this was favourably received. An *ad hoc* committee was formed to discuss the constitution of the new association.

Opening the first session of the meeting, Professor Balasse (Brussels) discussed the concept of the electron, linking it to the many classical theories of physics and developing from it the theories of corpuscular and wave motion. He concluded with a brief survey of the special applications of nuclear physics in medicine. M. Govaerts (Liège) then described some of the biological effects of radioactive substances.

The third speaker, Dr P. Bauwens (London), gave a concise account of his work on the study of action potentials in muscle. He described his own apparatus and his method of recording minute differences in electrical potential. Magnetic tape recording was used so as to store for subsequent analysis some of the irregular and transitory signals from muscles. His apparatus was built to a large extent from surplus war equipment.

Professor Dacos (Liege) in his lecture drew a parallel between electronic calculating machines using many thousands of radio valves and the human brain. The first session ended with a brief account of some of the results achieved by Dr Sofia da Conceicao Quintino (Lisbon) in treating arteriosclerosis by short-wave therapy.

### Electromagnetic Micro-waves

The second session was opened by Professor Rylandt (Brussels), who spoke on the significance of physical and biological electrotonus and described the action of polarizing voltages on muscle fibres and other body tissues. The remainder of the second session was devoted to lectures on terrestrial magnetism, climatology, and on the recording of ultra-violet rays from the sun. These papers were read by members of the staff of the Brussels Meteorological Observatory. The secretary of the meeting, Dr L. Konings, spoke on the problem of atmospheric ionization and its relation to cosmic rays.

The third session was opened by Dr Tomberg (Brussels), who described the different destructive effects of electromagnetic micro-waves. He showed slides revealing the destruction of capillaries by such waves. While mentioning briefly their use for destroying microbes, he concluded his talk by suggesting that recent developments had given us the means of producing such waves in lethal strength at a distance of 100 metres, and had thus brought nearer their application for warlike purposes. It was an odd reflection on human progress to learn that a mediaeval suit of chain-mail would afford good protection.

Professor Homes (Brussels) discussed the application of ultrasonic waves. He outlined the physical properties of these pressure waves at frequencies above 20 kc, and said that the science of ultrasonics as applied to medicine was still in its infancy. Much work remained to be done before quantitative results could be discussed in detail. Professor Casanova (Algiers) read a paper on the practical problems of amplifying electronically the feeble voltages and currents met with in electrocardiography and similar studies.

Professor Guckelberger (Zurich) showed a film demonstrating intramuscular and intravertebral galvanism. He had found that such treatment gave beneficial results in cases in which other

methods of physiotherapy and even, bipolar galvanism had failed. Dr Seguin (Paris) gave an account of his work on the biological applications of electromagnetic micro-waves. He demonstrated by slides the effect of these waves on the growth of various tissue cultures and gave details of their absorption by different kinds of body tissue.

#### Oscillographic Studies

At the beginning of the fourth session a note from Professor Coblenz (Washington) was read apologizing for his absence. Among other items, his paper on 'the dosage measurement of ultra violet rays' reported progress in developing a photo-electric cell for measuring the intensity of ultra-violet solar and sky radiation. Professor Cignolini (Italy) then gave an account of his work on determining the correct dosage to be used in short-wave therapy. Professor Arienti (Italy) presented a paper on his oscillographic studies of human motion. He described the arrangement he had devised to provide visual signals indicating the contact between parts of the feet and the ground while walking. These signals were recorded photographically and synchronized with the action potentials of the various muscles under observation. The information thus provided was of value in the treatment of patients suffering from the after effects of poliomyelitis.

Dr Bernard (Paris) described a novel method of treating lumbago and sciatica by the use of 'dia-dynamic' currents. These are low-frequency unidirectional, sinusoidal current pulses, and it was claimed that their use had effected improvement in the majority of cases. No ill effects of any kind had been observed over a period of one year during which this new technique had been tried in a Paris hospital. Professor Coppée (Liege) compared the characteristic excitability of nerve fibres to the properties of an electrical oscillating circuit. Dr Maury (France) dealt with the study of electrical charges on the skin, and Dr Burger (Utrecht) concluded the session with an account of his work on vector cardiography. He represented the electrical potentials due to the heart action by means of vectors and was thus able to record not only the amplitude of those potentials but also their direction relative to the body structure. His ingenuity in constructing a phantom of the human body out of clay deserves mention. This phantom was filled with a suitable electrolyte and an 'electrical' heart was introduced to generate the appropriate electrical potentials. After substitution of other body structures, such as bones and lungs, by suitable electrically equivalent materials he was able to measure the distribution of electrical charges in the phantom. Such studies, he said, might afford valuable data in comparison with measurements on living tissues.

The proceedings of these four sessions of the 'Medical Electronics' section of the Twenty-second Medical Congress will be published in full in *Acta Physiotherapica et Rheumatologica Belgica*.

#### EPSOM COLLEGE

The annual general meeting of the governors of Epsom College was held at 49, Bedford Square, WC1, on July 9, and the report of the council for the past year was unanimously approved.

Lord Leverhulme, who presided, spoke of the rising cost of education in all types of schools. The fact that there were at present 511 boys in the school—the highest on record—and that fewer than 20 had been withdrawn as a result of the increased fees showed that the value of an education at Epsom was appreciated by parents. Speaking of the agreement to take five boys a year from primary schools, in accordance with the recommendations of the Fleming Report, he said that it had become necessary for the school to be inspected by the Ministry of Education. Lord Leverhulme had no doubt that the inspectors would report that Epsom was sound in mind and limb and active in brain and intelligence.

The president said that the school was fortunate in having as a neighbour one who was a native of Epsom and at the same time a noted authority on education. He referred to Mr Chuter Ede, the present Home Secretary, and expressed the delight of all on learning that he had consented to join the governing body.

## PUBLIC HEALTH AFTER THE WAR MINISTRY'S ANNUAL REPORT

In more spacious times the report of the Chief Medical Officer of the Ministry of Health, surveying the field of epidemiology and the more personal public health services, and the annual report of the Ministry itself, dealing with housing, local government and the less strictly medical and more administrative side of the department, were issued as separate volumes at different times of the year. To day the two reports are combined in a slender document of 200 pages. This has the slight disadvantage that the two parts relate to different periods. Vital and medical statistics are prepared for calendar years and the annual report now issued covers 1946, whereas the administrative side of the Ministry measures its affairs according to the financial year and carries the story to the end of March 1947. As a further complication, some of the medical figures such as those showing the trend of short-term sickness, and the account of the cholera epidemic in Egypt and the precautionary measures taken here, relate to last autumn. With events moving so fast in the medical world, 1946 seems a long way back, and much of what is set out in the present report is only of historical interest.

#### Vital Statistics

The first complete post-war year was one of steady progress in public health. The birth rate (19.1), the highest for 22 years repeated the pattern of the years immediately following the previous war, though not with so high a leap. In 1920 the birth rate went up to 25.5. The population of England and Wales in 1946 was estimated to be over 40 millions, a figure which it had not reached since 1939. Persons over 65 comprised 11% of the population, compared with 9% just before the war. Infant mortality (42.9 per thousand births) was the lowest on record. In the corresponding year after the first world war it was nearly twice that figure. Maternal mortality (1.43 per thousand births) also reached its lowest level. Ten years previously the figure was 3.19. The death rates for the principal infectious diseases were all down except for influenza (of which there was an epidemic early in the year) and whooping cough, which with 93,000 cases and 808 deaths remains a stubborn problem in the epidemiological field. The noteworthy decline in the number of deaths from diphtheria—472, as compared with 2,861 in 1938—gave testimony to the effectiveness of the immunization campaign which began in 1941–2. The death rates for children from scarlet fever (there were only 43 deaths from scarlet fever in England and Wales), measles, and rheumatic fever were extremely low, this is attributed to the diminished virulence of current strains of haemolytic streptococci, though no doubt the improved care and nutrition of children are potent factors. During the early part of the year there was a recrudescence of smallpox, due to the heavy return traffic from India. Of the 56 cases reported, 14 were fatal.

Tuberculosis, though it is still responsible for nearly one third of all deaths at ages 15 to 39, shows a remarkable improvement. The total number of deaths from all forms of this disease in 1946 was 22,847, only one-third of what it was eighty years ago when the population of England and Wales was only half what it is now. One feature is the recent increase in the mortality rate from tuberculosis among men over 65, due presumably to the reactivation of lesions which might have remained dormant but for the strains and stresses of war. A similar tendency has been observed in other countries. In Sweden there has been comment on the displacement of mortality towards the older age groups. This country has still some progress to make before it equals the figures for the United States and Canada or for the white population of South Africa.

On the use of streptomycin the report states that it is already clear that this new weapon varies greatly in its effects on different individuals and in different forms and stages of the disease, that it is in no sense a substitute for other forms of treatment, but merely an adjuvant and that in view of its

<sup>1</sup>Report of the Ministry of Health for the year ended March 31 1947 including the Report of the Chief Medical Officer on the State of the Public Health for the year ended December 31 1946. London: H.M. Stationery Office. 3s. 6d. net.

limitations and potential dangers it should be used at present only under strict supervision

The blot upon the record for 1946 is the spectacular increase in syphilis, explained by the return from overseas of millions of men of the age groups most likely to be infected. The number of new cases of syphilis among males attending the centres doubled as compared with the previous year, and the number of male cases of gonorrhoea increased by something like 75%. The incidence of female cases of syphilis rose only slightly and those of gonorrhoea fell.

To glance at other diseases, there were substantial decreases in the mortality from dysentery and diabetes, smaller decreases in cerebrospinal fever, encephalitis lethargica, and pneumonia, and a very small increase in typhoid and paratyphoid fevers. Acute poliomyelitis was not the problem that it became in 1947. The number of cancer deaths registered was 75,407, in more than half these cases the site was the digestive organs and peritoneum.

This picture of the nation's health in 1946 has its gloomy patches, but it is encouraging for a year in which many of the unhappy effects of the war were still evident, a year of difficult readjustment and also of food scarcity a year which saw the introduction of bread rationing, a measure avoided during the war. The clinical and other surveys undertaken by the Ministry suggested no particular ground for anxiety, but Sir Wilson Jameson writes:

"There is no doubt, however, that the dietary restrictions inevitably experienced by the large mass of the people produced psychological, if not physiological, reactions. The most vulnerable groups were adolescents and others engaged in heavy manual work without access to industrial canteens, and, most of all, mothers of families."

#### Short-term Sickness

The Government Actuary contributes a report on short-term sickness. During the war there was a sharp increase in short-term sickness, becoming general in 1942 and continuing until the middle of 1945, after which it diminished gradually, until by the autumn of 1947 the relatively low pre-war level was almost regained. The method of computation has been to take the average number drawing sickness benefit per 1,000 insured persons. If there is incapacity of longer duration it is assumed that this will for the most part relate to persons no longer on the books of employers. Taking 100 as the figure for 1936-8, the ratio in the third quarter of 1947 was 104 for men, 106 for spinsters and widows, and 83 for married women: these ratios being in each case the lowest since 1940 or 1941.

In another part of the Ministry's report, however, a somewhat different story is told. This gives the results for each month of 1946 of the social survey of adult sickness. During the spring and summer of 1945 there was a very pronounced fall in minor complaints—colds, influenza, respiratory illnesses—the fall being no doubt connected with the ending of the war but such ailments again reached a high level by the end of 1946 and apparently throughout that year there was an increase in more serious illness among elderly women. A short table shows the number of medical consultations on account of certain diseases:

	Sex	Average No. of Medical Consultations in a Month per 100 People aged	
		16-64	65-
Affections of veins	M	0.2	1.6
	F	0.7	0.2
Rheumatism all forms	M	3.1	7.8
	F	3.2	5.3
Heart and arteries	M	1.6	10.6
	F	1.2	6.4

The loss of working capacity in a month at ages under 65 caused by varicose veins was equal to about 1½ days per 100 people and by affections of the heart and arteries about 2½ days. From all kinds of illness and injury the average monthly days lost per 100 individuals were 114 for men and 86 for women.

The year 1946 found the medical staff of the Ministry (who number by the way, about 150, of whom some 20 are part-time) largely engaged in planning and discussions relating to the National Health Service Act. In the hospital field the year

saw the running down of the Emergency Hospital Service and the bringing into focus of the new Regional Boards. A chapter of the report is devoted to the chronic sick, who occupy something like 70,000 beds in the hospitals of England and Wales. The report urges that more could and should be done to rehabilitate a large proportion of these patients, at least to the extent that they no longer occupy hospital beds.

"Doctors and nurses treating the chronic sick should not adopt a defeatist attitude, but should try to do as much as possible in rehabilitating persons who may still have some years of useful life before them."

The new Public Health Laboratory Service, which is the permanent reincarnation of the emergency service operating during the war, is the subject of a chapter by Prof. G. S. Wilson. It is hoped by means of this service to form an epidemiological network superior to anything yet experienced in this country.

In connexion with the insurance medical service attention is drawn to the rise in the cost of insurance prescribing. In England an average of about 4½ prescriptions were issued per insured person in 1946, a slight decrease compared with the previous year, but the average total cost per prescription increased by 7.4%, due largely to the use of expensive drugs such as penicillin, the sulphonamides, and synthetic preparations.

Other interesting matter in the report concerns the National Blood Transfusion Service, the World Health Organization port health administration, and the work of the Ministry in housing, water supply, and sewage disposal. The most up-to-date contribution is a description by Dr. L. H. Murray of the cholera outbreak in Egypt and Syria towards the end of last year and of the travel restrictions and prohibitions imposed by other countries during the outbreak. Thanks to the effectiveness of the measures taken not a single case occurred in Europe or on board ship or aircraft, but Dr. Murray is evidently of opinion that indiscriminate and unnecessary impositions in excess of international agreements were placed on travellers and merchandise which had little effect beyond creating a temporary chaos.

## NUTRITION OF ATHLETES

### NUTRITION SOCIETY CONFERENCE

A conference on "The Nutrition of Athletes" was held on July 17 at the Royal Society of Medicine, with Professor J. R. Marrack in the chair.

Dr. Philip Eggleston spoke on the physiology of muscular activity. Studies had been made on intact animals, notably man, on the surviving muscles of cold-blooded animals, and on muscle extracts from warm-blooded animals. A robust man could metabolize carbohydrate so as to derive 4,000 calories daily above his basal metabolic rate, but although carbohydrates were the most direct source of energy most heavy workers, such as miners, preferred meat and fat. Meat provided B vitamins—it was also a source of creatine, which was absorbed by the muscles, temporarily checking the excretion of phosphate. According to Hill a trained athlete might use up to 4 litres of oxygen per minute in violent exertion, but for constant activity only about 1 litre per minute was possible. To provide for the maximum consumption of oxygen the heart worked at eight times its resting capacity, achieving this by increasing both the rate and the volume of blood pumped at each beat. The athlete, however, might use energy at up to 100 times the resting level, and in doing so might incur an "oxygen debt" of up to 16 litres. When such large debts were incurred the underlying biochemical change was the conversion of glycogen to lactic acid. With smaller debts, however, no lactic acid was formed, and the energy was presumably derived from the decomposition of creatine phosphate. The deciding factor in athletic events lasting for minutes was the efficiency of the heart and lungs in supplying oxygen, but in events lasting only for seconds a low viscosity in the muscles was the most important factor.

Mrs. Dorothy M. Needham, F.R.S., said that the main sources of energy in muscular action were the conversion of glucose to lactic acid and the breakdown of creatine and adenosine phosphate. These reactions presumably occurred in series, leading finally to the conversion of adenosine triphosphate to the diphosphate. Adenosine phosphate had been

found to cause physical changes in the muscle protein myosin. The presence of actin, another muscle protein, emphasized these changes. Muscular contractions might be induced by a folding up of the myosin molecule.

Group-Capt C A Rumball described the selection of air crews. Candidates with low weight-to-height ratios had usually poorer expectations of health than heavier men, but even when a stone under weight cross-country runners were a notable exception to this rule. They might also be perfectly healthy even with diastolic blood pressures of rather more than 90 mm Hg.

Dr Geoffrey H Bourne discussed the value of vitamins for efficient muscular effort. Vitamin B was directly concerned in carbohydrate metabolism in the decarboxylation of pyruvic acid, while it was probable that most other B vitamins were also implicated in some phase of muscular metabolism. Could it be assumed that the athlete's requirements for B vitamins were raised in parallel with his increased metabolic activity? If so were his requirements for these factors satisfied by an ordinary diet? Trials in which extra vitamins had been administered with a view to improving physical performance had given conflicting results, but he thought Olympic athletes might well be given additional B vitamins as a precaution. Present views on the nutrition of athletes, and the obsession for large amounts of protein in the form of meat, seemed to him to be fifty years out of date.

### Diets for Athletes

Sir Adolphe Abrahams questioned whether athletes required much extra food and, if so, whether any special foodstuffs were desirable. Trainers had emphasized the value of meat, particularly beef, as the mainstay of the athlete's diet, but the reason for this preference was obscure. The value of the moderate use of alcohol had also to be considered. Genuine attempts must be made to reconcile the results of scientific experiments with knowledge gained by practical experience in feeding athletes, but it was highly undesirable to justify unorthodox methods of nutrition by pseudo-scientific explanations. Many athletes were highly imitative in their dietary habits. If some brilliant performer adopted a bizarre diet and won his event in spite of his tastes others would attribute his success to the food he ate, and promptly follow his example.

Sir Adolphe commented on Schenk's report on the enormous amounts of food consumed at the Berlin games in 1936. The total average daily consumption of 7,300 calories seemed to be incredibly high, and corresponded to an output of work equal to running 100 miles at moderate speed, or 5-6 hours of more violent exercise. Nothing approaching this amount of work was ever expected of Olympic athletes while in training. Thus a sprinter, visiting the track twice daily, might on each occasion make five or six bursts of 20-60 yards from his starting blocks, and then stride 150 yards at three quarter speed. His energy consumption for these activities should not total more than 400 calories. Marathon competitors might use up more energy in walking 10-15 miles daily, with occasional long runs, but they would still fall far short of justifying Schenk's report of their calorific requirements.

It might seem remarkable that in spite of their more strenuous training long distance athletes usually ate much less than their sprinting colleagues, and the explanation of the desire of some athletes for a liberal meat diet probably lay in the personal "make-up" of the sprinter type. Long-distance athletes were usually placid and phlegmatic, and were prepared to suffer toil and discomfort in any weather for hours on end. Sprinters, oarsmen, and others taking part in shorter events were more "highly strung" and restless in disposition, and often found the rigours and deprivations of training very irksome. Under these circumstances plenty of appetizing food, perhaps with some beer and an occasional bottle of champagne, helped to ward off "staleness," since this bugbear of all athletes seemed mainly mental in origin. Possibly the liberal diet also supported a higher metabolic rate.

Animal protein was enjoyed by athletes as much as by most other people, but apart from its psychological value it was not clear to what extent it was really needed. The performances of the great Finnish runner Nurmi had been quoted, as evidence that athletic prowess was not inconsistent with vegetarianism, but it must be remembered that he consumed liberal

amounts of milk and other dairy products. It might be expected that dosing with sugar would be valuable in long races in which the glycogen reserves of the body were exhausted, or in short races in which glucose was used up more rapidly than it could be derived from glycogen. Attempts to confirm this conclusion, and to test the value of dosing with vitamins and other nutrients, had been made difficult by the great susceptibility of athletes to psychological influences. Dosing even with a placebo might sometimes improve the athlete's performance merely by increasing his confidence in his own ability.

Sir Adolphe finally suggested that the causes of the steady improvement in all records for athletic events during the last fifty years were to be found not in better nutrition but in superior methods of training and increased competition. Really great athletes did not seem to care what they ate. In training for past Olympic games the British teams usually subsisted on quite ordinary diets, at only one-third to one half of the average level of calorie intake reported by Schenk.

Dr Herxheimer said that athletes, like mountaineers, might have a great desire for sugar after exertion. Major G C Arneil agreed that nervous strain might greatly increase the desire for food, on the evidence of the intense hunger caused by parachute jumping.

### Individual Variations

Dr Neville Leyton emphasized the widely different food consumptions of individual competitors in the same events. In long events the extra calorific output necessitated might be considerable. A boat race of 4½ miles might use up 500-600 calories in twenty minutes; a marathon race 1,800-2,000 calories in two and half hours, while a long set of tennis might require 1,200 calories. After such exertions, moreover, several hundred more calories might be expended during the next twenty-four hours before the pulse rate returned to normal. Training must continue for some months, and must aim at bringing the competitor to the peak of his form on the day of his event. The diet should contain bread, meat, eggs, potatoes, greens, and plenty of oranges and fruit of all kinds to prevent constipation. Tea and coffee were best omitted. In preventing staleness an increase in the fat content of the diet with a reduction in protein, might be useful. On the day of the event most competitors preferred to race on an empty stomach, but others felt faint, or even vomited, unless they had recently taken a little food. Glucose, barley sugar, or candy might be useful between events.

Dr R D Lawrence stated that in the present games competitors were unable to obtain glucose tablets, and had asked the Society to use its influence to make adequate supplies available. It was decided, however, that no action should be taken.

Professor Marrack summarizing the days' proceedings referred to the air of mystery which in the past had surrounded athletes' diets. At school he remembered a boy who was reputed to train on "raw beef and gunpowder." Later he had studied a famous book which recommended a diet from which all sources of vitamin C seemed to have been rigorously excluded. Then Emden, realizing the importance of phosphoric acid in the metabolism of muscle, had advocated sodium phosphate to increase stamina, although its main value was as an aperient. Possibly too much had been said about the production of energy and too little about its application. The high jumper must not only raise his centre of gravity as far as possible from the ground but by intense muscular co-ordination must arrange that no part of his body was very far below his centre of gravity at the precise moment of crossing the bar. In regard to diet the two chief points seemed to be the provision of enough food and the choice of food which could be readily digested. No competitor with indigestion could hope to excel in the Olympic games.

A problem which may be of considerable importance to public health is foreseen by the United States Department of Agriculture. Entomologists working for the department have developed a strain of DDT-resistant house flies. The strain is now in its 35th generation, and flies in each successive generation have required increasingly greater amounts of DDT to kill them. Though it has been reported in some parts of the United States and in other countries that house flies are becoming more difficult to kill with recommended applications of DDT, so far as is known no such DDT-resistant strains of house flies occur in nature.

## Reports of Societies

### RECOLLECTIONS OF LISTER

Some interesting personal recollections of Lister were brought forward at a meeting of the Section of History of Medicine of the Royal Society of Medicine on June 2

Dr H C CAMERON described how his father, the late Sir Hector Cameron, was a house-surgeon at Glasgow in the 'sixties when Lister was there, and later was Lister's assistant and remained his friend throughout life. Dr Cameron said that his own contact with Lister was occasional and fleeting and occurred when he was very young, but he had listened to Lister's talk in the intimacy of his own fireside, and he was brought up in a home where Lister's name was revered and where all that concerned him was of vital interest. His first recollection was in 1886, when Lister paid a few days' visit to his father. He remembered him standing, teacup in hand, with his back to the fire. In what he could recall of Lister he was nearly always standing. He stood, not because he was restless, but because he was absorbed in what he was saying or what was being said. He was never awkward or ill at ease. Dr Cameron spoke of Lister's quietness, his precision, his reticence, his courteous austerity, though in the wards he had usually some little jest which he shared with his patients. Once a small urchin in the wards, as his eyes followed Lister's movements, confided to a bystander, 'It's us wee yins he likes best and next it's the auld women.' The "wee yins" and the "auld women" knew nothing about great figures on pedestals, and his response to them was easy and natural.

#### Queen Victoria's Abscess

Dr Cameron went on to say that after he became a student at Guys in 1902 he liked to remember that Lister twice asked him to dinner. On the first occasion his father was staying with Lister at Park Crescent, on the second he was alone, and Lister told him in somewhat greater detail than was given in Godlee's book the story of the first use of rubber drainage tubes in surgery. He said that he was hurriedly summoned to Balmoral to treat Queen Victoria, who had developed an abscess. On arrival he made the necessary incision and inserted a wick to help the drainage. The result was not satisfactory—her temperature rose and she suffered great pain and discomfort. As he walked in the grounds of Balmoral—whenever Lister had a problem to settle he walked, pondering the situation—he thought of a possible device. He had brought with him a primitive form of his carbolic spray—Richardson's "atomizer"—to which was attached a long piece of rubber tube. Returning to the castle, he cut off a suitable length of this rubber tube and soaked it all night in a 1 in 20 solution of carbolic acid, using a soap dish in his bedroom for the purpose. In the morning he inserted it and found that it answered its purpose so well that recovery quickly followed. 'If,' added Lister, 'you ever hear anyone complaining that in hospitals patients are sometimes experimented upon, you may think of that story though you must not tell it.'

To his wife, Agnes Syme, a gay and gracious spirit, Lister owed a great debt. Dr John Brown, author of *Rab and His Friends*, spoke of Lister's wedding and said of Lister that he believed he would go to the very top of his profession, and as for Agnes she had a 'bit of heaven about her'. Lister without his wife was always apt to be oblivious of time. It was no unusual thing when there was interesting research afoot for him to forget professional appointments altogether. Agnes helped him in many practical ways as well as by her calm confidence and buoyant spirit which made light of the setbacks of the moment. She had also a keen sense of humour and unfailing high spirits and the unpunctuality and over-careful preparation of her husband never made her impatient. He was not the same man after her death.

A characteristic episode was Lister's diligent search for an absorbent dressing. After combing the shops of Glasgow he eventually found what he wanted in the book trade, in book-binders' muslin, a fabric which could be impregnated with carbolic acid. But he still wanted a suitable material for insertion between the seventh and eighth layers of gauze to

spread the discharges evenly over the antiseptic pad, and thus he found in the hat trade, in a hat lining which, to distinguish it, he coloured pink. This is the material sold to day as jaconet and generally dyed pink, as Lister originally directed.

Dr Cameron read extracts from some of Lister's letters to Sir Hector Cameron showing how great was the havoc wrought in his state, both of body and mind, by the loss of his wife, whom he survived twenty years. "In his solitary old age all the unhappiness, misunderstandings, and ridicule of the past occupied his mind far more than the applause of nations and his ultimate triumph." His last letter to Sir Hector was dated April 23, 1911. "I am very grateful for your kind birthday greetings. You will excuse me not saying more."

Dr Cameron concluded "It has been said that there is but one division to be made in the history of surgery—surgery before Lister and after Lister. It is right that his name should be revered and his work known and right that we should do what we can to picture him to ourselves in his ordinary daily life, ceaselessly experimenting unceasingly preparing, and always beloved."

#### Letters of a Young Disciple

Dr E ASHWORTH UNDERWOOD followed with an interesting short paper in which he quoted from some letters of a young student who was in Lister's class and living in his house during the year of Lister's appointment to the chair of surgery at Glasgow (1860) and the years immediately following. The student was Marcus Beck, whose father was a paternal cousin of Joseph Lister. Marcus Beck, who became a brilliant surgeon and inspiring teacher, was born in 1843, entered the university of Glasgow in 1860, qualified in 1865, became assistant surgeon at University College Hospital, teacher of operative surgery in 1875, and professor of surgery in 1885. During the first three years of his studentship he lived with the Listers at 17 Woodside Place. The collection of letters to which Dr Underwood has had access—the letters of a student to his family—number 34. Among them was an enthusiastic description of an operation by Lister at Glasgow Royal Infirmary on Nov 30, 1861.

"The operation [lithotomy] was one of some difficulty, and he was somewhat nervous about its success during the week. But on the morning of its performance he was perfectly cool and comfortable. The theatre was crowded from the roof to the area, and there were several practitioners from the city present. I was awfully excited, as I knew even the best men might sometimes find difficulty in that operation, and Joseph Lister's reputation as a surgeon depended in some measure upon his success. But my fears were soon quietened by seeing him perform the operation to the admiration of all present in 1½ minutes. It was a most beautiful sight, and one I could watch for an hour with pleasure if it could be repeated. He was tremendously applauded by the assembled multitudes. He then performed an amputation of a big toe with its metatarsal bone with similar success. When he appeared at his surgery class the same morning he was received with tremendous cheering and clapping, showing the approbation that the students had for his magnificent performance."

In many other letters Beck referred to Lister's operations, all of which were done "beautifully". In 1862 he described how they did six cases in one day. These letters, of course, were all too early for any references to Listerism. Many other sidelights on Lister appeared in this correspondence. On Sundays Beck's usual recreation was a walk with Lister during which they did some botanizing. Beck obviously enjoyed himself thoroughly. On January 19, 1862 he wrote "The professor [Lister] is issuing invitations for his dinner party—it is only 12 days to it. My heart palpitates at the thought. I intend to do a swell with a white tie for the first time." From the very first the hero-worship shone from these faded youthful letters. In one of the earliest he said that he spent an afternoon helping Lister to unpack his museum. Beck was overjoyed when Lister got him—a youth of 18—to help him syringe ears or assist in operations on the foot or in a squint case. In a letter in 1862 he said that the professor was getting on beautifully in practice and that altogether he made £1,000 a year, and this was increasing daily.

Particular interest attached to Beck's comments on Lister's use of chloroform. Lister was extremely interested in this subject, as was fitting in a man who as a student had attended Lister's first public operation under chloroform at University College in 1846. Lister was the first to recommend pulling

forward the tongue to relieve stridor. From these letters and other sources it was evident that Lister prided himself on the good results which had been obtained in Scotland with chloroform by the open method. Down to as late as 1870 there had been no deaths under chloroform in Edinburgh Royal or Glasgow Royal, though according to Beck there was very nearly a death in 1861 at Glasgow, which was averted by the prompt intervention of 'J L,' who was only an observer at the operation.

Some brief discussion followed these two papers and Mr VERNON CARGILL, who was house-surgeon to Lord Lister and surgical registrar at King's College Hospital, added some further reminiscences.

## CARCINOMA OF THE CERVIX

### Surgery and Radiotherapy

At a meeting of the Edinburgh Obstetrical Society on May 19, with the president, Dr W F T HAULTAIN in the chair, Mr CHARLES READ read a paper on the role of surgery in the treatment of carcinoma of the cervix.

Mr Read said that there was a division of opinion on the relative merits of irradiation and radical surgery in stage I and stage II cases. There was little debate in respect of stage III and stage IV cases, which were generally unsuitable for surgery. While in many clinics the Wertheim operation was abandoned when radiotherapy was generally established, at the Chelsea Hospital for Women this operation had been performed continuously since Mr Bonney introduced it in 1907. From the published statistics even the surgical enthusiast had to admit that the results of radiotherapy compared favourably with those of surgery, but the question might well be raised whether any of the fatalities after radiotherapy could be avoided by judicious surgical procedure. Mr Read suggested that there were seven indications for surgery in carcinoma of the cervix. These were: (1) radio-resistant growths proved either clinically or cytologically, (2) columnar-celled carcinoma of the cervix, (3) vaginal vault stenosis, (4) the presence in addition of large fibroids or ovarian cysts, (5) an associated salpingitis, (6) refusal of irradiation by the patient, and (7) pregnancy in the presence of a cervical carcinoma. After discussing each of these indications separately Mr Read considered the Wertheim operation after previous irradiation. Although this did increase the technical difficulties the operation was justifiable in proved radio-resistant cases, experience in the Chelsea Hospital showing a five-year survival rate of 44.4% in 34 stage I and 20 stage II growths.

From a study of material obtained at the Wertheim operation, at necropsy and at the operation of lymphadenectomy without removal of the uterus Mr Read had come to the conclusion that the rate of gland involvement was approximately: stage I, 20 to 25%; stage II, 30 to 35%; stage III, 40 to 50%; and stage IV, over 60%. From these figures it would appear that treatment by radium alone, using vaginal applicators only, could never hope to give adequate radiation to the lymphatic field. It therefore seemed that there was a place for iliac lymphadenectomy in stage III cases which had been treated locally by radium, and that such a procedure could well be extended to include stage II cases and selected cases of stage I growth.

Mr Read discussed the Wertheim technique with particular reference to the carrying out of lymphadenectomy early in the operation, leaving the iliac and obturator lymph node chain attached to the uterus throughout. He stressed the need to remove at least the upper half of the vagina, and emphasized the value of plasma or blood transfusion. He recorded an incidence of post-operative urinary fistulae of 3.1%.

### Limitations of Radiotherapy

Professor ROBERT MCWHIRTER said that at one time there had been sharp differences of opinion between surgeons and radiologists but increasing experience had narrowed the area of disagreement considerably, and further study might yet obliterate it. His own opinions were governed not only by technical details but also by certain general principles. Of these he placed first the need to consider each case of cancer individually, and to treat the patient and not the tumour. The prime object should be to make her more comfortable,

any treatment which cured the cancer without achieving this end was a failure. The maximum distance from the cervical canal at which radium might be expected to be effective was 3 cm. Growths which extended beyond that distance were not susceptible to radium. The dosage varied for different tumours and some might justifiably be described as radio-resistant, but the most important limiting factor in regard to treatment was the restricted striking distance of radium. Radio sensitivity was a variable factor, and at the moment the opinion of the histologist was of limited value in its recognition, a new approach to its histological study was necessary. Observation of the effects of irradiation in successive biopsies might possibly prove a valuable field of investigation. It was difficult to envisage any great increase in radium range in the near future, apart possibly from improved applicators with more efficient screening of the bladder and rectum. It was the need to avoid damage to these organs which chiefly restricted the dosage.

When x-rays were first used to supplement radium treatment the whole pelvis was irradiated. Not uncommonly necrosis developed in tissues which had already received a high radium dosage. It became obvious that if x-ray therapy was to be really beneficial it must be closely related to the radium treatment. Patients with cells just outside the effective range of radium were far more likely to benefit from x-rays than patients with cells far out in the pelvis, for these latter advanced cases frequently had distant metastases as well. In order to try to align the two methods of treatment the x-ray fields were planned from radiographs showing the position of the radium in the uterus, but when vaginal packing was introduced the uterus might be greatly displaced to one or other side of the pelvis and it might also be displaced upwards to a considerable extent. These difficulties could to some extent be overcome by the use of special radium applicators such as those devised by Richards, of Toronto. X-ray therapy alone would remain an unsuitable method of treatment until much more powerful apparatus became available.

Professor McWhirter believed that surgery was the most effective method of treating cancer when it was early and localized. Unfortunately, by the time patients sought advice the condition was often no longer suitable for treatment by surgery. In criticism of some of the claims made for surgical treatment he pointed out that a number of factors operated to produce a favourable selection of cases. For example, the patients submitted to surgery were usually in good condition, not unduly obese and not too old, and were stage I or early stage II cases. Because extensive lymphadenectomy must always remain a piecemeal dissection, he thought it unlikely that this operation would greatly improve the eventual prognosis. He did not believe that an inoperable case could ever be rendered operable by preliminary irradiation, although he believed improvement might be obtained by means of post-operative irradiation with very high voltage x-ray apparatus. In operable cases pre-operative irradiation might be of benefit.

In a review made some time ago the five-year survival rate in Edinburgh was 29% of all cases referred. In the cases most recently analysed the five-year survival rate was 34%. In the calculation of these survival rates no case was omitted from the total for any reason whatsoever. He believed that these figures might be improved by the use of surgery where the disease was early and where the tumour was shown to be radio-resistant, and he thought a serious attempt should be made by histologists to recognize resistant tumours so that the appropriate treatment might be given initially.

Mr Read's paper was further discussed by Dr DOUGLAS MILLER, Dr E C FAHMY, Dr CLIFFORD KENNEDY, Dr J C CLARK, Professor MARGARET FAIRLIE, Dr R DE SOLDENHOFF and Professor R J KELLAR.

The Minister of Health, after consulting the Civil Nursing Reserve Advisory Council, decided to accept their advice that the Civil Nursing Reserve should cease from July 5. Its effective members have been absorbed into the general establishment of nurses in the National Health Service. All members in employment on the appointed day retain their existing salaries until these are overtaken by increments on the scales of the ordinary nursing staff. Nursing auxiliaries may retain their present title and pay so long as there is no comparable grade in the general nursing establishment to which they could transfer.

## Vasodilatation

There is considerable evidence of the outstanding value of Cardophylin in producing vasodilatation. The coronary vasodilatation is manifested in an increased coronary blood flow and a beneficial effect on the myocardium, the renal vasodilatation is indicated by the powerful diuretic. It also causes bronchodilatation.

## Preparations and Appliances

### A MOUTH SCREEN FOR USE AFTER ADENOIDECTOMY

Professor E. MATTHEWS, honorary prosthetic dental surgeon, Manchester Royal Infirmary, writes: At the clinical meeting of the Manchester Medical Society held in June 1947, I demonstrated the use of the mouth screen or oral shield as a form of follow-up treatment after the removal of adenoids—the object being to correct the mouth breathing habit. I found a considerable interest taken in this simple appliance, and have since had requests from several doctors for advice for their own children.

The appliance can easily be made from a sheet of "perspex" or celluloid moulded to shape, or from the moulding powders used in denture construction. The only requirement is an impression of the labial surface of the upper and lower teeth

as far back as the first molars. The idea is by no means a new one, and some dental surgeons have for long used the mouth screen as a simple but effective orthodontic appliance for the treatment of over prominent front teeth. The appliance is of course only used at night, and functions as a valve. It prevents mouth breathing since in the act of breathing in through the nose it moves into contact with the gums, thereby acting as a seal. The inward movement is conditioned by the slightly reduced pressure (below atmospheric) in the oral cavity during the act of breathing.

Professor Sprawson (*Brit Dent J* 1947 83 231)

states: Many still appear to think that if the nasal obstruction is removed that is all that need be done, but experience does not bear this out. During the day nasal breathing may be re-established if the child is admonished when seen with its mouth open, but it invariably reverts to mouth-breathing at night, and unless treated this habit will persist throughout life. He also comments on the association of an anterior gingivitis with the mouth-breathing habit, and insists that 'it is a serious complaint because it is almost always a precursor of parodontal disease, with its oral sepsis and early loss of teeth'.

There are therefore important dental and developmental reasons why every care should be taken to see that the mouth-breathing habit is properly cured after the immediate cause—adenoids—has been removed. It would be interesting to know what steps are ordinarily taken by ones ENT colleagues to terminate this habit. The use of sticking-plaster over the lips is an obvious but usually unwelcome solution of the problem and therefore for the majority of cases I subscribe to Professor Sprawson's dictum that 'every child who has the adenoid operation done needs this treatment (oral screen) as otherwise the habit persists'.

An attractive booklet on first aid entitled *ABC of First Aid* has been written for the British Red Cross Society by Air Marshal H. E. Whitincham. Line diagrams on the left-hand pages illustrate simple first-aid manœuvres such as artificial respiration, removing a foreign body from the eye, splinting limbs, and controlling bleeding. Explanatory notes are tabulated in alphabetical order on the right-hand pages and at the end there is a list of the commoner poisons, the symptoms they cause, and the first-aid treatment required. The pamphlet will be useful in the home, on the highway, and in industry.

## Correspondence

### Golden Jubilee of the R A M C

SIR—It was gratifying to find that our modest *Scrapbook* should have been deemed worthy of a notice in your columns, and I should like to assure Dr W. C. Souter (July 10 p. 107) and your readers that we in the Corps are by no means insensible of the great part played by the B. M. A. in the shaping of our destiny. During the compilation of the *Scrapbook* I read with the greatest interest Sir Alexander Ogston's 'bombshell' and its many repercussions. We felt however that it would more suitably be included in some authoritative history of the Corps than in a very ephemeral light-hearted publication which included among its readers many hundreds of young recruits.

A further reminder of the contribution made by the B. M. A. to the efficiency of the R. A. M. C. has been provided by a correspondence which I have been having with Dr C. H. Milburn of Harrogate, who is the sole survivor of the special Committee on Army Medical Reform (1896) and who formed one of the deputation to Lord Lansdowne which resulted in the formation of the Corps 50 years ago. He has been good enough to lend us a copy of the Draft Report as submitted to the Parliamentary Bills Committee and many other documents of absorbing interest, extracts from which we hope to quote in an early number of our Corps magazine. In this number too, we will endeavour to do belated justice to the work of Sir Alexander Ogston. That the B. M. A. of those days certainly did not "pull its punches" is very obvious from the following quotation:

"We have thus considered how the Army Medical Service satisfies the four essential conditions which we laid down at the outset. It satisfies none of them. In other words, it is at present in the most unsatisfactory condition. Justly discontented, with duties and responsibilities second to none in importance, but without the Army status necessary for their proper fulfilment, exposed to hardships and dangers in excess of those in any branch of the Army, yet without the military recognition which others receive, with an undue amount of foreign service, with no opportunity for advancing their professional knowledge, or the slightest encouragement to do so, with an anomalous and disjointed relationship between men and officers, and in face of indefinite postponement of reform, it is no wonder that the British Army Medical Service is on its way to extinction. It is impossible for anyone acquainted with this state of things to regard with equanimity the prospects of a great war. If such a calamity were to overtake us it is difficult to see how we could avoid the utter collapse of the medical arrangements. A spectacle of misery and mortality to equal which we must look back to the horrors of the Crimea would not be a matter for astonishment. Only two forces seem ranged against Army medical reform: (1) unwise economy, (2) unreasoning prejudice at the War Office."

In this our jubilee year it is especially fitting that we should remember that the efficiency of our Army Medical Service and indeed the victorious outcome of two world wars were due in large measure to these far-seeing and forceful members of the B. M. A.—I am, etc.,

### Sir Patrick Manson

SIR—As former pupils of Sir Patrick Manson and as members of the original London School of Tropical Medicine which he founded in 1899 we would like to thank you for your reference (July 10, p. 82) to the predominant part that he then played in the elucidation of the transmission of malaria for by so doing you have placed this subject in its proper historical perspective.

We have always regarded his paper in your *Journal* in 1894 (2 1306)—'On the Nature and Significance of Crescentic and Flagellated Bodies in Malarial Blood'—as the starting point of the modern knowledge of malaria and as one which led to the successful accomplishment of a great venture without which the working out of this intricate problem could hardly have been achieved at that time—We are, etc.,

PHILIP MANSON-BAHR

### The BBC and the NHS

SIR,—The BBC could hardly allow the inauguration of the National Health Service to pass without contributing a pep-talk. This took the form of a dramatic discussion in the Light Programme on July 6 at 8.30 p.m. For the benefit of those who missed this enlightenment and inspiration here is a summary.

First we heard a mother's dread of the voluntary hospitals transformed into joyous confidence in the same hospitals nationalized. Then, the existence of the voluntary hospitals being conveniently forgotten, we heard how the wife of a gas-works employee had for years refused surgical treatment to her varicose veins because she could not afford the surgeon's fee.

The hero of the piece was a surgeon basking in his own self-righteousness, high mindedness, and other-worldliness. To him came a Mr Venables, intended to be a typical *nouveau riche* or no doubt his modern equivalent, a Tory lower than vermin. He wanted to know whether he should remain a private patient or become a public patient. The hero delivered a moral lecture in the best Pecksniffian manner. But, though eloquent on the evils of the past, he hedged deplorably when questioned about the future. Mr Venables, seeing through this tirade, decided to remain private. His decision appeared to me to show his astuteness, but the intention of the script writer was evidently the opposite. Incidentally, we heard the old fiction, so sedulously propagated by the Socialists, that the *malade imaginaire* is found exclusively among the wealthy and that the poor suffer only real illness.

Playing opposite to the hero was the villain, personified of course by the medical superintendent. Trouble had arisen in the bad old days over a case of torticollis, a woman with her neck "twisted right round" (presumably through 180°, not 360°). The superintendent was for discharging her, but the hero nobly stood his ground, thereby risking his career in the interests of humanity. Baffled, the superintendent suggested exercises. Again "No" from the hero, who, however, had no suggestion to make except masterly inactivity. The problem was solved by the patient's suddenly dropping down dead. "Tuberculosis of the atlas." Curious that x-ray examination twice failed to reveal any abnormality in a neck with the head facing the wrong way. The Light Programme is hardly a place wherein to expect logic. The lesson appeared to be that under the old dispensation a patient with torticollis of unknown cause was discharged from hospital if she survived exercises but under the new would be left to die in her own way. Believe it or not the piece was intended to be serious and good propaganda. It is a saddening reflexion that despite the millions spent on its education democracy should be considered and no doubt is, capable of believing such nonsense—I am, etc.

Cambridge

FF ROBERTS

### Acute Intussusception

SIR,—The article by Drs Brenda Morrison and Donald Court (April 24, p. 776) has brought to mind the six cases of acute intussusception in children and young adults which came under my care during 1947.

**Case 1**—A schoolboy, aged about 14 years had abdominal pain and vomiting of 28 days' duration. Four days before admission each attack was accompanied by defaecation, and the patient had ten motions the day before admission. Helminthiasis was diagnosed and he was given medicine, but did not pass any worms although the bowel moved thrice. The abdomen was rigid and painful to the touch. At operation an entero colic intussusception about eight inches long was discovered in the left splenic flexure surrounded by inflamed and adherent omentum. It was irreducible, and as there was apparently no obstruction it was decided that there was no need for any further interference, and the abdomen was closed. The patient gradually recovered and was discharged fit from hospital 24 days after admission, the intussusception having undergone spontaneous cure.

**Case 2**—A farmer, aged about 30 years, complained of abdominal pain and vomiting seven days before admission. There was no obstruction and the bowel moved once or twice daily, indeed, it moved five times on the 5th day of admission. Palpation revealed a sausage shaped abdominal tumour across the epigastrium. At operation an ileo caecal intussusception was discovered in the epigastrium and was reduced by milking. The caecum and appendix were oedematous. The patient made an uninterrupted recovery. He was discharged 34 days after admission.

**Case 3**—A male child, aged 10 years, had abdominal pain and vomiting seven days before admission. In this case also there was no obstruction as the bowels opened three or four times daily in hospital. The abdomen was soft and a sausage shaped tumour was palpated. An ileo caecal intussusception was discovered and reduced at operation. The patient made an uninterrupted recovery and was discharged 13 days after admission.

**Case 4**—A male child, aged about 12 years, had a history of abdominal pain and vomiting of one month's duration before admission. The patient was very emaciated and dehydrated, due to excessive vomiting. The abdomen was rigid and tender, and the patient was constipated. At operation an irreducible entero colic intussusception was discovered, with the omentum and the small intestine wrapped round it. As there appeared to be an obstruction in this case a short-circuit operation was performed with a view to resecting the intussusception later, but the patient died 12 hours after the operation.

**Case 5**—A schoolboy, aged 8 years, was admitted with pain in the abdomen and vomiting, particularly after food which started 18 days before admission. Examination revealed a sausage shaped abdominal tumour across the epigastrium. There was no rigidity and the patient's condition appeared fair. It was decided to operate at once, and at operation an ileo caecal intussusception was discovered in the region of the hepatic flexure. It reduced readily by milking, although the caecum appeared very oedematous. This patient died on the third day after operation for no apparent cause.

**Case 6**—A 25-years-old male had abdominal pain and vomiting of nine days' duration before admission. He too had a sausage shaped abdominal tumour, but there was no rigidity and no obstruction. An ileo colic intussusception which occupied the right side of the abdomen was reduced at operation, and the patient made an uninterrupted recovery and was discharged from hospital 25 days after admission. (All the cases were operated on under spinal anaesthesia.)

From a consideration of these cases the following points emerge.

1 Obstruction does not appear to be an early feature of this disease in young adults. Case 4 was the only one with definite obstruction, and in this case there was a history of abdominal pain and vomiting of one month's duration.

2 Although the ileo ileal variety is generally regarded as being more common after the age of 3 years, the anatomical variety met with in all these cases was the entero colic type.

3 The passage of blood and mucus, which is regarded as one of the cardinal signs of the disease in children was not met with in any of the cases.

4 All the patients in this series were male.

5 Acute intussusception is generally regarded as a disease met with in infants up to two years, and in its chronic form in adults—generally over 60 years. Although this series is too small to justify any definite conclusions, it is nevertheless well to bear in mind this condition in considering the differential diagnosis of acute abdominal conditions in children and young adults, at any rate in tropical Africa.

The predisposing factor in these cases is most likely the fact that the African peasants' diet consists mainly of carbohydrates—yams, cassava, and corn—which give rise to fermentation in the large bowel and gaseous distension of the bowel. Any condition which causes violent peristalsis like injudicious diet or violent purgation would drive the ileum into the roomy ascending colon. The late onset of obstruction and gangrene in these cases, and the fact that most of the intussusceptions reduced so easily in spite of their duration, lend support to this theory, as, owing to the width of the colon, the ileum could enter it with part of its mesentery without its blood supply being obstructed.

I am indebted to the Director of Medical Services, Nigeria, for permission to publish these cases.

—I am, etc.,

Oshogbo Nigeria

M A MAJEKODUNMI

SIR,—I was very interested in the article on acute intussusception in childhood by Dr Brenda Morrison and Dr Donald Court (April 24, p. 776), but it was disappointing that they gave so little attention to non-operative treatment in early cases. From force of circumstances I was obliged to try the old-fashioned method of inflation with air on the only two cases I have seen in this remote settlement in northern Canada with results so dramatically successful that it seems a pity that it should not be tried in all early cases even when facilities for operation are at hand. Since the reduction can be attempted under the anaesthetic given to confirm the presence of the tumour and requires no elaborate equipment or skilled assistance, the loss of time in trying it is very small and in

use of failure no harm has been done. Where the baby lives or from a hospital the method can be life saving as I think the histories of my two cases prove.

**Case 1**—October, 1943. The patient, a white girl of 17 months was a strong healthy baby. She awakened at 6 a.m. screaming with pain, vomited a little clear fluid, refused food, and during the rest of the morning slept between attacks of crying with pain. Early in the afternoon a little blood stained mucus was found on her nappy. When I saw her soon afterwards she was pale and collapsed, with a weak, rapid pulse but no fever. Her mother told me that when rubbing the baby's abdomen in an attempt to ease the colic it had seemed to her that the left flank felt empty. This was not noticeable when I examined her, and I felt nothing abnormal, but on rectal examination I found the apex of the intussusception just inside the anus and it was visible as the baby strained when I withdrew my finger.

Prolonged autumn rains had made the ground too soft for an aeroplane to land, so that the alternatives were either a 36 hour journey to hospital carried on a saddle horse over rough bush trails, or operation by me, single handed, with the aid of an amateur anaesthetist. Neither appeared to offer much chance of life to a shocked baby. It seemed justifiable to attempt reduction by inflation with air.

At 4 p.m., about ten hours after the onset, under an anaesthetic administered by a neighbour, I introduced a small rubber catheter alongside the intussusception, attached it to the bellows of a Junker's inhaler, and pumped very gently while compressing the buttocks to prevent the return of the air. The resistance could be easily felt by the hand. After keeping the pressure steady for a minute or so there was a clearly audible "plop," heard by the anaesthetist as well as myself, and there was no further resistance to inflation. A few minutes afterwards, before the child was fully awake, she had a large normal bowel movement, preceded by a little blood stained mucus. The baby's recovery from shock was most dramatic, within half an hour she appeared perfectly normal. She has never had any illness since then.

**Case 2**—April, 1946. The patient, an Indian boy aged 15 months, was a particularly husky baby. At 10 a.m. he suddenly vomited and complained of pain in his abdomen and cried at intervals all morning. At 2 p.m. his mother found about a teaspoonful of bright red blood on his diaper, but no faeces. When I saw him at 3 p.m. he was very pale and lay limply on the bed with eyes half closed. Every few minutes he roused and cried in obvious pain. His temperature was normal, pulse 130 and very weak. His abdomen was very tender to palpation but I thought I could feel a tumour on the right side. He vomited a little clear yellowish fluid while I was examining him. The rectum was empty and there was only a little blood and no trace of faeces on the examining finger.

On this occasion a snow storm made it impossible to get him out to hospital by air and, remembering the previous case, I decided to try inflation again if examination under an anaesthetic confirmed the presence of the tumour.

Six hours after the onset of symptoms under an anaesthetic the classical sausage-shaped tumour could be clearly felt extending from the right iliac fossa to the border of the liver. By the same method as before the bowel was very gently inflated. The line of the colon could be clearly seen to bulge. After a few minutes the swelling gradually disappeared though the buttocks were firmly held to prevent the return of the air. A further slight pressure on the bellows produced no feeling of resistance to the hand. An hour later the baby was still sleeping peacefully, his colour good and pulse much stronger. By 9 p.m. he was sitting up playing and had no further pain or vomiting and looked quite well. The bowels were opened the next morning, there was a slight stain of brownish blood on the diaper and a small amount of faeces containing raspberry seeds and paper. The stool the following day was absolutely normal with no trace of blood. The child has never been ill since.

—I am, etc.

KET-PINE, Alberta

MARY PERCY JACKSON

### Megaloblastic Anaemia of Pregnancy

**SIR**—The two cases described under the above title by Drs M. Gillespie and A. M. Ramsay (May 1, p. 828) are of intense interest to all haematologists but it is questionable whether they should be grouped with the classic macrocytic anaemias of pregnancy. The proportion of myeloblasts in the blood and marrow is against that diagnosis while the clinical haematological and necropsy findings are in keeping with the small group of cases which can be classified as of the 'leukaemia syndrome'. The distinction is important in that the classic cases of macrocytic anaemia of pregnancy respond to appropriate

treatment or to the termination of pregnancy, while leukaemia progresses to the fatal end. Though the term leukaemia is one of convenience rather than one of diagnostic exactitude, it is interesting to note that Gillespie and Ramsay postulated a possible maturation factor defect involving myeloid as well as erythroid cells. This is a conception of the condition to which H. Fox, A. Kondi and I (*J. Clin. Path.* 1946 58 157) were also forced in considering such a case some years ago—I am, etc.

Johannesburg

JAS. F. MURRAY

### Urological Surgeons in Conference

**SIR**—In your report (July 10 p. 85) of the Annual Meeting of the British Association of Urological Surgeons held at the Royal College of Surgeons from June 24 to 26 no reference has been made to the papers read by two distinguished honorary members. The discussion on urinary lithiasis was opened by Professor Hellstrom of Stockholm, a leading authority on its aetiology. The following day a paper was read by Dr. Michon of Paris, on the repair of exstrophy of the bladder with restoration of continence. Both these papers will be published in full in the September number of the *British Journal of Urology*.

Professor Hellstrom was the only official guest but although no special invitations to attend the meeting were sent to colleagues abroad Professor Fey and Dr. Michon of Paris, and urologists from Italy, Portugal, Spain, Sweden, Turkey, and Uruguay listened to the discussions. This was a tribute to the prestige of British urology.

Besides these guests the members of council had the pleasure of welcoming Mr. Mortensen, President of the Australasian Urological Association, Mr. Thomson Tait of Melbourne and Mr. Keith Kirkland, of Sydney, N.S.W. The policy of developing and co-ordinating the medical resources of this country for the benefit of our colleagues throughout the world is already beginning to bear fruit. In conclusion, may I congratulate the B.M.A. on the formation of the Empire Medical Advisory Bureau—I am, etc.

CLIFFORD MORSON

President, British Association of Urological Surgeons

London W.1

### Clinical Records

**SIR**—Mr. Malcolm Donaldson (July 3 p. 47) has pointed out the essential weakness in the statistical analysis of medical records. I would suggest that it would help to improve their value if these were compiled in a form that would be of practical help to the clinician and thus enlist his interest. To expect the clinician to fill up a complex form which is rendered to some central bureau for analysis by statisticians is exasperating to him and does not encourage his interest. If the form were such as to be of practical value to him accuracy would be encouraged.

It was with this idea in mind that I devised the record card described in the *Lancet* (1947 2 189) which was based on the Copeland-Chatterton system. This allows for adequate coding and cross references for a moderate-sized hospital department but it is cumbersome to work in large numbers and would be quite inadequate for a record bureau, where obviously mechanical sorting is necessary. If the initial analysis of clinical records could be done on such a record card the information coded thereon could be transposed to a punch card system for use at a central bureau and the record card could remain at the disposal of the clinician for study of his own cases. I have already described the value of such record cards to the clinician in the above-quoted letter—I am, etc.

Cheltenham

C. P. DONNISON

### Paludrine

**SIR**—Having used 'paludrine' prophylactically and therapeutically for just over a year I have been unable to substantiate the rather I think excessive claims made for it. Having been in the habit of taking 5 gr. (0.32 g.) of quinine daily for over twenty years during the war I changed to mepacrine, with about equal results. When paludrine became available in early 1947 I changed to that drug as neither quinine nor mepacrine had kept me sufficiently free from malaria of a mild type in a highly malarious district. I started taking 0.1 g. paludrine twice

a week then three times a week, then on alternate days, then daily. I have taken 0.1 g daily now for approximately eight months and the results are about equal to those of quinine or mepacrine.

As regards those under my care, the result has not been happy. In the highly malarious port of Bonthe during 1947 I advised those Europeans who consulted me, and who were taking quinine or mepacrine, to try paludrine in the recommended dosage of 0.1 g twice a week. Three went down with smart attacks of malaria within a month, parasites being found in one instance. Other Europeans suffered less severe attacks under the same regime, parasites were found in one case. Those who wish to take paludrine I now advise to take 0.1 g daily. A number of Europeans have returned to their former quinine or mepacrine, and I am not now advising those already taking these drugs to change to paludrine if they are satisfied. Except in my own case, I have not been able to follow up the after history of those taking 0.1 g paludrine daily.

Therapeutically paludrine seems at least equal to quinine or mepacrine, though I prefer to give two 10 gr (0.65 g) doses of quinine at the start of an attack, giving at the same time 0.1 g paludrine three times a day, and continuing with it in this dosage for ten days. I do not say that initial dosage with quinine is a necessity, but it still seems the best drug to bring down the temperature quickly.

In spite of this not very eulogistic account of paludrine, nevertheless I prefer it both prophylactically and therapeutically to either quinine or mepacrine. In the highest dosage tried, that is 0.1 g prophylactically and 0.1 g therapeutically once and thrice daily respectively, it is certainly not inferior to the other drugs and has the advantage of being apparently free from any toxicity in the therapeutic dosage tried. I can myself carry on with my full activities after at most 48 hours' treatment, and usually earlier, and I have had no complaints of unpleasant reaction from patients. The same cannot, emphatically, be said of quinine, and not always of mepacrine. Its freedom from dyeing the skin is also an advantage of paludrine.

Paludrine is a valuable drug which should not be allowed to fall into disrepute when it may be that merely a change in dosage and/or regime may be required. I see the manufacturers have altered the recommended dosage somewhat, but 0.1 g twice a week would not seem to presage much improvement since in my own case even 0.1 g daily is not completely protective. I propose to try 0.3 g in one dose once a week (as also recommended by the manufacturers) and work from that. It may be that a comparatively large dose taken once or twice a week may work better. I might add that in my own case and that of a number of others an attempt was made to sterilize the blood first with a full therapeutic course of 0.1 g paludrine thrice daily for ten days before continuing with it prophylactically, but I have not found this makes any difference. The air wants clearing as regards this drug, and I should be grateful for the opinion of practitioners of experience—I am, etc.,

### Odd Legs

SIR—Although I did not read Dr Nesta H. Wells's original letter, the communication of Captain Robert Fuller and Lieut Douglas L. Woolf (July 10, p. 109) interested me personally, since at the age of 12 years I was sent to see the late Mr T. H. Openshaw about the increasing deformity of my left foot due to infantile paralysis, and he pointed out to my parents that the  $\frac{3}{4}$  in (1.9 cm) shortening of the limb was causing curvature of the spine. I remember thinking that a spine anyway was pretty much given to curvature, but my parents obediently saw to it that my left heel was raised  $\frac{1}{2}$  in (1.3 cm) and my right heel lowered  $\frac{1}{4}$  in (0.63 cm). At that time I also had some sort of a tarsectomy done to stabilize the ankle, and incisions in the plantar fascia—the whole procedure being to correct a fairly well marked equino-varus deformity. The boot prescribed was of the customary type with an iron up the inner side.

Two or three years later, my headmaster, Dr J. R. C. Greenlees, seeing my keenness for chasing balls and recognizing perhaps the possibilities of an exceptionally powerful right leg, suggested that I might take up rugby again. The late Sir John Fraser, whom I consulted, did not forbid me, and he pointed out to my parents that the contractures of the calf muscles had exactly compensated for the shortening of the leg. I could not of course stand to attention with both heels on the ground. I presume therefore, that it was fortunate for me that the plantar and not the dorsiflexors of the foot were paralysed. By

a simple adaptation of the boots I was able to continue playing full back at school and later for my hospital ward. In the same way cricket, hockey, etc., presented no difficulty. Tennis, however, proved a problem, since on no type of court are boots welcome. For some years I wore a galosh over my left boot but after a time, when I found I could not beat the other members of the family, I became exasperated. So taking an old worn out boot I performed a Syme's operation on it and began to wear an ordinary gym shoe together with the "stump" in order to give my ankle support. It was entirely successful.

During six years in India I very soon—after about five weeks—gave up any attempt at wearing boots, because of the heat. I had a modified pair of sandals made which were very comfortable and light, and were ideal for ordinary hospital work. However, after six years of sandals I found that my original foot wear was intolerable, so I searched Edinburgh for a boot which would give me some of the advantages of those sandals, and now I get "odd" factory made boots, the left being two sizes smaller than my right. Since my left boot pre-war cost about £5, this is also a considerable saving of expense. The fact that I must wait 3–5 months for delivery might seem a disadvantage, but I sometimes waited nearly that long for a boot to be specially made for me.

No doubt over the past 15 years facilities have vastly improved and ideas become more generous in their outlook. It is our job to see that the "lame man shall leap as an hart" and that "the tongue of the dumb shall sing"—even if the lameness and the dumbness remain. Better a deformed limb useful than a straight one loaded down with theory—I am, etc.,

### Vaginal Injury at Coitus

SIR—The following case of a vaginal vault-injury due to normal coitus in a young parous woman may be of interest in view of a previous article in the *BMJ* of April 24 (p. 786).

#### CASE REPORT

A tall, well developed married female of 17½ years old, 1 para, 3½ months post partum, was admitted complaining of severe haemorrhage per vaginam which had begun during intercourse. She also complained of slight pain in the lower abdomen. The incident occurred one hour before admission.

Her period had been due on the day of admission, but the present loss was in no way like her menstrual loss, being much more rapid, with brighter blood, and of sudden onset. Pulse rate 116, and of diminished volume. Respiration 24, temperature 99°F (37.2°C), BP 115/80. The patient was pale and conjunctivae were poorly coloured. The abdomen was soft and there was very slight tenderness over the pubis. The uterus was not palpable per abdomen. Per vaginam the external os was closed and the cervix was firm and "non-pregnant". The vagina was packed with gauze in the receiving ward, and the patient was sent to theatre.

The possibilities considered were trauma, abortion, and sub involution of the uterus. Instructions were given to "try up" for a possible repair, vaginal packing, or dilatation and curettage. The patient was examined under a general anaesthetic and the introitus was found to be of a parous type, with a small amount of unrepaired perineal tearing at delivery. An Auvard speculum was inserted and inspection showed the vaginal vault to be somewhat retracted. The cervix was closed and not bleeding. High in the posterior fornix there was a linear laceration 2 in (5 cm) long, extending from one lateral fornix to another across the vault. The floor of the laceration was composed of vascular cellular tissue, and peritoneum was not visible. The vulsellum forceps were transferred to the posterior lip of the cervix, and by holding this up excellent exposure was obtained. Eight No. 1 catgut interrupted sutures coapted the edges and completely arrested the haemorrhage. The area was sprayed with penicillin powder.

The patient made an uneventful physical recovery, although there appeared to be a certain amount of residual emotional trauma. Haemoglobin on the fourth day was 66%. She was discharged in seven days.

#### DISCUSSION

The patient was interviewed both on admission and after operation in regard to the use of artificial appliances, birth control apparatus, etc. The use of these was denied with apparent honesty and sincerity. The husband was also interviewed separately, and bore out his wife's statements. Intercourse was in the dorsal decubitus position. The husband permitted examination of himself, and there was no undue enlargement or distortion of the parts. The patient was a tall well built woman, and there was no question

of disproportion. Factors which might contribute to this accident are those which depress the fornix. A shortened perineum from severe perineal tears would diminish the height of the vaginal vault. Uterine prolapse with or without rectocele would predispose similarly. Physiologically a simultaneous contraction of abdominal wall and diaphragm would raise intra-abdominal pressure and momentarily depress the pelvic diaphragm.

Another factor to be considered is the part her recent pregnancy may have had in softening and vascularizing the parts. Since this case I have heard of another similar one at 6 weeks post partum. On the other hand a case is described by Nicholls of an adult female with similar injury 8½ months post partum, when complete involution should have occurred. Three cases are described in the *Medical Journal of Australia* of 1919, two by D Arcy, and one by Stokes. Other similar cases are described by Anspach, Ricciardi, and numerous others. All cases are characterized by hemorrhage severe enough to threaten life and which usually requires surgical repair for its arrest. The literature contains a goodly number of cases of this type, but most textbooks devote only a few lines to this subject, if it is mentioned at all.

The leading textbooks describe coital injuries as occurring primarily at the vulva and hymeneal areas, and sometimes extending upwards from this. Injuries high in the vagina are usually said to occur in old women or young girls.

I should like to express my thanks to Dr C D Coyle Medical Superintendent of the Archway Hospital, and Miss Harding consulting gynecologist, for permission to publish this case.

—I am, etc.,

#### Use of Ring Pessaries

SIR—During the past three years I have reviewed a large number of old women, some not so old, who have collected at the right and bobtail of my out-patients and form that neglected and pathetic army dealt with haphazardly by the house-surgeon or the out-patients' sister—the 'ring pessaries'. It will be comment enough, I think, to report that this large army has now been reduced to three. Fifty-seven have undergone some form of colporrhaphy or vaginal occlusion their ages ranging from 37 to 84, with a mortality of nil and a happiness of 100%. Fourteen have had their rings removed—they were unnecessary. Of the remaining three, two are quite unfit for operation and the third prefers to lead her ring life. It would seem, therefore that three out of seventy-four ring pessaries were necessary somewhat less than 5%. This percentage in terms of the whole country, indicates at least the urgent need for a critical review and it is therefore desirable to lay down the conditions in which ring pessaries should be used.

A ring pessary is the facile answer to any woman complaining of a bearing down feeling, though this may be due to anything from a cervical polyp to a urethral caruncle. There is therefore great necessity for an accurate diagnosis or even an eliminating diagnosis. There are three types of cases to which rings are generally fitted. The first and probably the most pathetic are the young women who have descent of the vaginal walls in the immediate weeks following childbirth. The usual train of thought is that these walls must be supported until the 'involution' of the vaginal tissues reduces the 'prolapse'. This is an outstanding example of muddled thinking. A ring pessary, surely, if it has any effect produces this by stretching the vaginal walls. To apply a ring in these cases is therefore to produce the very condition we wish to avoid apart from the mental, physical, and marital discomfort that accompanies its use.

The second type of case is the middle aged woman in which there is permanent descent of one or both vaginal walls. To them the ring pessary is fitted in their thousands without reference to the relative degrees of uterine or vaginal prolapse, to the presence or otherwise of stress incontinence which no ring could possibly help, and very often without reference to the state of the cervix. I have seen more than one carcinoma of the cervix treated with a ring pessary. The truth is that the doctor is in a difficult position. Although he may feel that a surgical cure of the prolapse is desirable the woman because of domestic difficulties fear of operation and so on declines his advice and his only alternative is to fit a ring which of course does bring comfort in many cases.

The third type of case is where because operation is out of the question a ring pessary is the only treatment. May I plead,

therefore, that ring pessaries, except perhaps in this last category, with their stink and their dangers be put on the bonfire of last year's gynaecological garden? May I plead with even more entreaty that the Hodge pessary in the treatment of "retroversion" be put away altogether and for ever from our minds and our uses?—I am, etc

London W 1

MORTIMER REDDINGTON

#### Antenatal Care

SIR—There has been a great deal of correspondence in the medical journals and in the daily press on the relief of pain in childbirth and it is generally agreed that fear and anxiety often lead to a painful and difficult labour. The best way to allay the apprehension which many women have towards their confinement is for them to know and have confidence in the doctor or midwife who is going to undertake their case.

The main purpose of antenatal care is, I consider, not only to diagnose and treat any abnormalities, but to get to know the mother, to allay her fears to confound the old wives' tales and, as the time of delivery approaches, to gain her complete confidence, which will lead to co-operation in the actual labour. There seems to be a tendency nowadays to allow antenatal care to become a cursory affair. The National Health Service (General Medical and Pharmaceutical) Regulations, 1948, state on p 16 that 'in the case of maternity medical services all proper and necessary treatment shall include advice in regard to antenatal supervision, antenatal care including an initial medical and obstetric examination and an examination at the thirty-sixth week of pregnancy or at any time that the practitioner thinks necessary'. In other words the doctor can attend a mother in labour after having met her only twice before. Antenatal clinics held by some local authorities seem to be run on these lines. One case I sent up with a letter asking to have an abnormality investigated was turned away by a clerk because she was only three months pregnant. Another case, thirty weeks pregnant was told that she need not attend again until labour commenced.

Some years ago I was a resident obstetric officer at an LCC hospital where we had a large maternity department and ran our own antenatal clinics. We asked our mothers to attend every month up to the seventh month, every fortnight during the eighth month, and every week for the last month of the pregnancy. During this time the mothers got to know the doctors and nurses well, and they were no strangers to us when they came into the hospital for their confinement. Our forceps rate over a series of about 600 deliveries was only 6%.

I have continued to carry out antenatal care on the above lines and have found that the knowledge and friendship obtained from these frequent consultations produces confidence and co-operation during labour, into which the mothers enter quietly and calmly and mentally at ease. This produces the relaxation which appears to be so necessary in alleviating the pains of labour. The analgesics, especially pethidine, have far more effect under such conditions. If I am allowed to continue the practice of midwifery under the new health service I shall see my patients just as frequently, for then I too can approach a confinement with the assurance that I am going to deliver a mother who, knowing me, will do her best to co-operate with me in a spirit of happy anticipation.

May I conclude by saying that the utility maternity service provided by the Ministry of Health at £7 7s a time (cheaper quality £5 5s), in which a doctor is required to see the mother only twice before labour and to attend at the confinement only if he thinks necessary is not likely to lead to the utopia of painless childbirth which certain correspondents in our popular press would have us believe has been attained by our colleagues on the other side of the Atlantic—I am, etc.,

J G FIFE

#### Comprehensive Child Health Service

SIR—May the following suggestions be brought to the notice of those interested in the development of a comprehensive child health service in this country? Our child health service, although better than in most countries, is still in its embryonic state. Nevertheless there is already an odd maldevelopment taking place—hereditary perhaps from the days when paediatrics formed a minor part of obstetrical teaching. This anomaly I feel is of an importance which cannot be sufficiently emphasized and which, allowed to develop, may for ever prevent the establishment of a satisfactory child health service. I am

referring to the fact that child welfare forms part of the maternity welfare service, and thus a sharp division is created between those occupied with prevention and those occupied with the cure of diseases of children

Three distinct services cater for child health at present the maternity and child welfare service (how reminiscent is this combination of pre-paediatrics days), the school medical service, the general practitioner. Considerable overlapping and confusion between these three services exists and is bound to increase as the welfare scheme develops—i.e., a mother will take her child to the welfare centre, where some ailment is discovered. The welfare M.O., respecting jealously guarded rights, cannot treat the child, although perhaps better qualified to do so, but has to refer the child back to its G.P. Such occurrences are numerous, and thus, although not wishing to pass any judgment on the relative abilities of welfare paediatricians and G.P.s, the child is deprived of the best service available. Surely the paediatrician, best qualified to deal with child welfare, is best qualified to deal with diseases of children. In other words, surely the person best qualified in the prevention is best qualified in the cure and *vice versa*, the person best qualified in the cure is also best qualified in the prevention of diseases of children.

I hope I have made myself clear. It seems absurd to have a maternity and child-welfare officer with a dossier of the child's health and the G.P. with a dossier of the child's diseases. I fear our babies may fall between two stools, and to prevent this from happening, to give our children the best available attention, the establishment of a comprehensive paediatric service is proposed.

The scope of this paediatric service would be supervision of child health from almost conception to 12 years, the school medical service forming part of the scheme. To translate the proposal into practice the following suggestions are offered:

(a) The appointment of one or more paediatricians for each community. Such a paediatrician—preferably, the holder of a D.C.H. and/or a higher qualification, or at present any G.P. with special experience in paediatrics working in co-operation with M.O.H. nursery school medical authorities, and child welfare workers—would be responsible for child health in his community and combine the functions of the present child welfare M.O. with those of the paediatrician.

(b) It is suggested that the Minister be approached to press local authorities to provide suitable accommodation for child welfare centres.

(c) That all children of the area be on the paediatrician's panel.

(d) Holding an appointment of such scope and responsibility he paediatrician ought to be allowed capitation fees for all the children in his panel, have an additional salary for his work as child welfare officer, and perhaps be also allowed paediatric beds at the local hospital, if such is feasible.

Among his duties would be ante- and post natal advice to mothers, propaganda on child health, including occasional lectures, child hygiene and nutritional problems, the toddler, etc., and, most important of all, prevention and cure of diseases of children.

The advantages are obvious, the opportunity unique. This would be the first country in the world having a complete paediatric service available to all children, including the toddler, who, too old for welfare clinic and too young for school, does indeed fall between two stools at present.

The disadvantages are few, and any pecuniary losses that may accrue to general practitioners are almost nullified by the fact that within the next few months most children will be insured. Quite on the contrary, a considerable burden—vaccinations, etc., etc.—will be taken off their shoulders. The only other disadvantages which I can see are that a mother may have to travel further to reach the paediatrician, but surely no mother will deny her child the best opinion available. Finally, the poor paediatrician: his indeed will be a hard lot until sufficient paediatricians are available, but I feel the goal is a noble one—at last a complete health service to the most important section of our community—our children—I am, etc.,

London E 11

P. O. CROSSFIELD

### Lower-segment Caesarean Section

SIR—It is always a risk to say that anyone was the first to propose anything in medicine, and Mr Bryan C. Murless (June 26, p. 1234) would appear to be in error in saying this of Frank with regard to lower segment caesarean section.

Osiander's operation in 1805, though crude and dangerous, was nevertheless a lower-segment approach. In 1881 Adolf Kehrer used a technique which differs only in detail from that of the present day. He incised the lower segment transversely but did not dissect the bladder downwards nor free an upper flap of peritoneum. This great advance was lost sight of, because of the success of Sanger's improved technique for the classical approach, until 1906, when Frank began to achieve better results still with his "suprasymphysial"—i.e., lower segment—operation—I am, etc.,

### RCS and Fellows' Opinion

SIR—Lord Webb Johnson's reply (*Journal* July 3, p. 46) ignores the essential point in our previous letter (June 26, p. 1258)—namely, his suppression from the medical profession of the resolutions passed at the Fellows' meeting on April 28. That suppression is maintained in Lord Webb Johnson's letter, in which, while mentioning the second and third resolutions, he does not disclose their nature—We are, etc.,

REGINALD L. MURLEY

REGINALD T. PAYNE

ALEX E. ROCHE

W. ETHERINGTON WILSON

SIR—We all regret the cleavage in our College over the Health Act. It may be that, as the President avers, some Fellows have a political axe to grind as well as scalpels to sharpen in Lincoln's Inn Fields. But most of us, regardless of party, are bent on sound surgical succour for all who need it. The profession painfully aware of the grave inadequacy of its services, had paved the way for reformatory measures. We thought our hopes were about to become realities. Instead we found the presented Act lacking in elements essential for the successful extension of "the study and practice of surgery." To protest against it became our solemn duty to the founders of the Royal College of Surgeons and the public—I am, etc.,

Bristol

A. WILFRID ADAMS

### Chemists' Working Hours

SIR—A few weeks ago I broached the question of chemists' hours for supply of urgent medicines. Some of your correspondents have supported me. Now you print (July 3, p. 49) a letter from a chemist who seems to consider that the comfort of a dispenser comes before the health of the people, that doctors keep patients waiting while they finish their game of golf, and that the B.M.A. is not concerned with seeing that the public is properly supplied with medicine. No further comment is needed on your correspondent's opinions.

I may be permitted to state that recently when I ordered some urgent medicine for a patient at 8 p.m. on a week-day the patient's brother cycled around for some time in this district without being able to find a chemist available. He then went to a West End chemist and had to call back in an hour and a half before he could have the medicine. Something is wrong here—I am, etc.,

London N.W. 11

L. S. WOOLF

The Ministry of Health reports that there are still a number of Government scholarships available for suitable State registered nurses and male nurses (general trained) who wish to train as sister tutors or male tutors. Applicants must generally have had at least three years' post-registration experience in nursing in hospital, including at least one year in charge of a ward in an approved training school. Those selected are given an allowance of £150 for the period of training (one academic year) towards the cost of maintenance and incidental expenses, and their training and examination fees are paid. Subject to certain conditions an additional allowance is payable to a married man in respect of his wife and any children under 16 years. Successful candidates must undertake to serve as registered tutors in a hospital of their own choice in Great Britain for a period of at least two years. The next courses of training will start in the latter part of September or early October, those who wish to apply for assistance under the Government scheme should write immediately to the Secretary, Ministry of Health, Division 3C, Whitehall, London, S.W. 1.

## Obituary

### W AUSTIN ROBB, M.D., F.R.C.P.

Dr W Austin Robb, who died at his home in Exeter at the age of 55 on July 12, had a remarkable career embracing three branches of medical science.

William Austin Robb was born at Burnt Fen, near Ely, in 1893. His first training was as a pharmacist, and he served St Bartholomew's Hospital in its dispensary before becoming a medical student there. Previously he had been with the 36th Field Ambulance as a sergeant-dispenser, and he had been wounded and taken prisoner in 1916. After qualifying in 1924 he became house physician to the late Sir Walter Langdon-Brown, whom he greatly admired and was subsequently to serve as chief assistant after an intervening period as demonstrator of pathology. He obtained the London M.D. and the M.R.C.P. in 1926. A career of uninterrupted success in medicine and his outstanding clinical ability then appeared to point clearly to a future as a consulting physician. It was therefore with some surprise that his friends heard of his appointment in 1931 as pathologist to the Royal Devon and Exeter Hospital, a position in which he continued for the rest of his life. He had had in extensive experience in clinical pathology in the two more senior appointments he held at St Bartholomew's and indeed he had always done for his own patients a great deal of laboratory work which most men less inclined in that direction or less enthusiastic, would have left to others. Nevertheless he was regarded as a clinician and indeed was a very good one; hence this decision to take up the appointment at Exeter was unexpected.

Austin Robb's subsequent career provided an outstanding example of the value to a clinical pathologist of a wide knowledge of medicine. He was the kind of pathologist who is not merely asked to perform specified investigations but is invited to make whatever investigations he thinks appropriate and to produce an opinion based on all features of the case, both clinical and pathological. In this capacity he became one of the leading figures in medicine in the West of England, and an undisputed authority in that part of Devonshire in which his responsibilities lay. He was on the staff of many hospitals covering a wide area extending even into Somerset. During the war he shouldered the added burden of organizing the blood transfusion service, a task which as Regional Resuscitation Officer he carried out with great efficiency. The exertions Robb imposed on himself may well have been a factor in the illness which caused his premature death. His other activities included frequent attendance at meetings of the Pathological Society and of the Association of Clinical Pathologists, of whose Council he was a member in 1942-4. He was also a member of the B.P. Codes Revision Committee, a position for which his varied experience made him exceptionally well qualified. He was a vice-president of the Section of Pathology at the annual meeting of the B.M.A. in 1938. He was elected F.R.C.P. in 1945.

Robb's personal popularity was well deserved. He had always the air of a countryman, simple, unpretentious, frank, and genial. His natural kindness must have been a major factor in his success in dealing with patients. He leaves a widow, a son, and a daughter to whom the sympathy of all his friends and colleagues will be extended.—L. P. G.

W. A. B. writes: Other people can write better about Austin Robb as a clinician-pathologist of the front rank, but may one of the many who benefited from his innumerable kindnesses write of his capacity for friendship? This survived many miles of separation and the lapse of many years. Through him my most prized distinction was obtained and for this no trouble was too great at a time when he must have known his inevitable end. Speaking the last time I saw him of a distinguished man who I rathered had helped me also, he said: "He is very generous with his largesse. If that was ever true of anyone it is so of that loved and cheerful Christian, Austin Robb."

D. A. H. writes: Austin Robb was one of the remarkable few of clinical pathologists who came to maturity between the two wars. These clinical pathologists were essentially forerunners who worked in the laboratory at the elucidation of clinical problems and even if the growth of specialization could not this type to extinction their value to the practice of

English medicine and surgery in the county hospitals has been outstanding. They taught the clinicians what questions should be addressed to the laboratory and how to interpret the answers. Robb was a well-known and much-loved figure at Bart's for more than ten years. Robb is too good a man to be allowed to leave London," said Langdon Brown when the time came to take another step up the ladder, and doubtless Robb would have valued an appointment to the Bart's staff. But he was essentially a countryman, and his appointment as pathologist at the Royal Devon and Exeter Hospital gave him an environment which exactly fitted his needs. On the edge of the City of Exeter, looking over a Devonshire valley, he made his home and out of the red earth of an old quarry he made his garden. To the building-up of a first-class laboratory in Exeter he brought an intense enthusiasm and an experience which equipped him fully for his task. His insistence on accuracy can only be described as passionate, and he was tireless in the pursuit of it in himself and in others. The extent of his work would have justified much writing, but he published little for his energies were absorbed in the continuous improvement of his pathological service. He was allowed private practice from the start, and later on his colleagues showed their appreciation of his quality by giving him charge of some beds. These privileges meant much to him, for he was stimulated by personal problems, and he brought an unusual humanity and generosity to his human contacts. It was this last characteristic which gave him a great company of friends, and many are to day saddened by his death in middle-age. Uncommonly fortunate in his work and in his family life, he knew himself to be unfortunate in his illness, and with courageous jesting he struggled against its inexorable grip. Not for him the folded hands, the passive resignation in the face of oncoming death. He died as he lived, and his friends unite in their thought of him as one who "should have died hereafter."

### F. McG. LOUGHNANE, F.R.C.S.

Mr Farquhar McGillivray Loughnane, the well-known urological surgeon, died at the age of 63 in St Mary's Hospital, Paddington, on July 14, after a long illness which he faced with critical detachment. Mr Loughnane was a student of St Thomas's Hospital, where he won the Treasurer's Gold Medal and the Peacock Scholarship, qualifying in 1912, and taking the F.R.C.S. in 1914. He will be remembered professionally for his work in urological surgery. He had strong individual ideas and is probably best known for his advocacy of radical operation in urogenital tuberculosis. He was a pioneer in the field of transurethral resection of the prostate, and was a past president of the Section of Urology of the Royal Society of Medicine.

During the 1914-18 war Loughnane held the rank of captain in the R.A.M.C. and among many other appointments was surgeon specialist to No. 40 B.G.H. in Mesopotamia, where, by carrying out the open treatment of fractures in desert conditions, he proved himself to be an able general surgeon. He held the appointment of surgeon for many years at All Saints Hospital for Genito-Urinary Diseases, he was assistant urologist at the Prince of Wales's Hospital, Tottenham, and urologist to the London County Council. He had been surgeon to St Mary's Hospital for Women and Children, Plaistow, for twenty-eight years and he was also a consulting surgeon to the Hampstead Cottage Hospital. At St Mary's, Plaistow, as at his other hospitals he was held in affection and esteem by all his colleagues—administrative, medical and nursing. He will be sadly missed and will leave a gap which will not easily be filled. At Plaistow he gave many hours of devoted work in both operating theatre and out-patients department, as well as on the board of governors and hospital committees. No one who was associated with him will ever forget his deep sense of duty in every department in which he was interested.

Loughnane was a keen member of the Irish Golfing Society and often showed his persevering character in this pursuit. He was a loyal and active supporter of the B.M.A., representing the Marylebone Division for eleven years apart from being chairman of the division in 1938-9. Loughnane's nature was a warm and affectionate one, and to those who knew him well it was always a pleasure to be in his company. He was a man with very definite views but always responded readily to those who needed his help. He leaves a widow, and the sympathy of all his friends will be with her.—G. H. R.

## Medical Notes in Parliament

### NATIONAL HEALTH SERVICE

MISS BACON described to the House of Commons on July 19 on the motion for the adjournment, what she called a medical black market which was being created by a minority of doctors who were discrediting and sabotaging the National Health Act by refusing to take on their lists patients who could afford to pay private fees or who needed special attention. Miss Bacon said it was common for a doctor to say to a person who had a sufficiently high income "I am sorry I cannot take you on my list, this scheme is not for you, you can afford to pay." That was an immoral discrimination which was a disgrace to members of a great profession, but even worse were those doctors who were refusing to take patients because they needed extra attention—the old, the sick, and children. She had heard of one case of a household where every member except the grandmother was taken on the doctor's list. Presumably she was refused because the doctor thought she might become bedfast and would need extra attention. She had heard, too, of doctors who had refused to take children because they were likely to get childish ailments. There was the more subtle but no less sinister approach adopted by the doctor who did not refuse outright to take patients but suggested to them that they would not get the same attention as paying patients. [The B.M.A. have asked for details of these cases.]

MR BEVAN said the practices described were carried on by a very small percentage of the medical profession. The vast majority were playing the game. It would be a great mistake if the majority of the profession were besmirched because of the conduct of a small number. It was wholly reprehensible for a doctor to select members of a family as patients and refuse others. Such conduct cut right across the conception of a family doctor. There was no justification for discrimination on financial grounds. If a person remained as a private patient he would also have to pay for drugs. That might have a chastening effect as time went on, as the knowledge grew it was possible that the area of private practice would diminish progressively. There were certain sanctions under the Act which could be applied where doctors said they could not take people on their lists and insisted on their being private patients or paying patients. Their areas could be regarded as under doctored. It was one of the functions of the Medical Practices Committee to attend to that matter.

### Confidential Certificates

SIR ERNEST GRAHAM-LITTLE on July 15 asked whether Mr Bevan knew that anxiety was felt by doctors at the increasing tendency of Government departments to disclose to lay persons the contents of confidential medical certificates furnished by practitioners in charge of patients. As the regulations in Statutory Instruments 506 and 507 required medical practitioners in the new health service to submit to a committee consisting predominantly of laymen records of patients under their charge, Sir Ernest asked Mr Bevan to withdraw this requirement.

MR BEVAN refused to do this and could not accept the implications of the question.

### Drugs and Appliances

MR RANDALL asked the Minister of Health on July 15 if doctors, under the new health service, would be free to prescribe for the patients without restriction, every kind of drug and appliance necessary for their treatment and would not have to work within the limits of averages of cost per insured person.

MR BEVAN replied that a doctor had a duty to prescribe under the National Health Service all drugs necessary for the proper treatment of the patient without any limit of cost whatever, also the appliances prescribed in the General Medical and Pharmaceutical Regulations. Other appliances were obtainable through the hospital service.

### Spa Treatment

SIR WALDRON SMITHERS asked the Minister of Health if, in view of the resignation of Dr McKenna, of Droitwich, he would make a statement on spa treatment under the National Health Service.

MR BEVAN thought this doctor might have been under a misapprehension. For patients of the appropriate hospitals in the National Health Service requiring treatment of the spa type it was open to a regional hospital board to arrange for convenient facilities for this treatment to be used, at the discretion of the medical staff of the hospital, to supplement the hospital's own resources. It was not a responsibility of the

hospital service to provide treatment at spa establishments otherwise than in this way.

### Medicines no longer Dispensed

SIR HENRY MORRIS-JONES asked whether any arrangements were being made to reimburse medical practitioners under the National Health Act in respect of the cost of drugs and medicines which would not now be required to be dispensed by them.

MR BEVAN replied that he had no proposals in mind but that in any case this would be a matter for the Negotiating Committee to take up with him first.

### V D Clinics

MR SORENSEN inquired why the statutory protection of secrecy had been withdrawn from persons attending V D clinics under the new National Health Service Act.

MR BEVAN said the withdrawal resulted from the revoking of the Public Health (Venereal Diseases) Regulations now that responsibility was transferred to regional hospital boards. He emphasized that treatment for venereal disease would continue to be as confidential as it always had been.

### FACTORIES BILL

The Factories Bill, which was first considered in the House of Lords, passed through the committee stage in the House of Commons on July 9.

MR ATTEWELL said Clause 7 allowed the "appointed factory doctor" to act in his old position as examining surgeon and was open to objection, although with the passing of the Industrial Injuries Act the temptation for a doctor to be biased in his decision was not present. Nevertheless, when a man desired to appeal to a medical examiner to see if his complaint was caused by his work, he should have no fear but that the decision would be in accordance with the facts as that medical examiner saw them. He submitted that it was dangerous for the appeal to go to a doctor not only closely connected with the firm on business grounds but also operating there from day to day.

MR ISAACS was satisfied that the charge could not be made against the profession that doctors gave certificates against their opinion. Whatever certificates they gave were given honestly and conscientiously. Most of the suspicion would disappear under the new Act, but the point was being raised because there had grown up a desire for a comprehensive medical service inside the factories. Where it was necessary for a certificate to be given under any of the Acts by the factory doctor the Government might see whether it could not arrange for another opinion to be brought into the picture. The Clause was ordered to stand part of the Bill.

MR MCCORQUODALE said on Clause 13 that it was time that Parliament in factory legislation began to differentiate between women and young persons. In the next Factories' Bill he hoped Parliament would consider that women were grown up.

MR ISAACS said this matter was under international consideration at present. It would probably become practical politics to make such a distinction before Parliament needed to revise the Factories' Acts.

MR PIRATIN brought up a new clause on weight-lifting. This provided that a person should not be employed to lift, carry, or move any load so heavy as to be likely to cause injury to him. He said many industrial accidents and illnesses were the result of strain in weight-lifting. The Minister had for eleven years possessed power to regulate weight lifting for different industries, but so far regulations had only been introduced for potteries, woollen industries, and flour mills. The regulations did not limit the time during which the lifting of heavy weights was to continue.

MR ISAACS said Mr Piratin had spoken against certain regulations and not against the terms of the Act itself. Regulations existed in the woollen worsted trade and were under consideration for jute. Under the existing Act the Ministry of Labour had all the power which was proposed in Mr Piratin's new clause. In leaving the powers as they were at present the Ministry had more latitude for dealing with the problem than would be the case if the words suggested by Mr Piratin were adopted. The proposed clause was negatived.

MR ISAACS thereupon promised to look into the subject raised in another proposed new clause on the safety of roof workers, and this clause was also withdrawn. So was a proposed new clause intended to include schools, technical colleges and other institutions where persons were instructed in the use of machinery in the term "factory."

The Report Stage then concluded and the Bill was read a third time after the Attorney-General had said that the Government was considering the possibility of consolidating the factory legislation.

## Hay Fevers CAN be relieved

Many cases of hay fevers which have hitherto proved resistant to all forms of therapy, can now benefit from the symptomatic relief afforded by

# 'ANTHISAN'

pyranisamine maleate

ANTHISAN is a new and powerful antihistaminic drug which has been specially developed for the relief of hay fever and other allergic conditions. It is a powerful antihistaminic drug which has been specially developed for the relief of hay fever and other allergic conditions.

MAY & BAKER LTD.

## IT IS A FORTUNATE HEAD THAT NEVER ACHED

For providing quick and lasting relief from headache of whatever origin 'Veganin' Tablets are especially useful because they do not prevent the patient from continuing his usual occupation. 'Veganin' does not cause drowsiness; it merely obliterates the pain and quiets the nervous manifestation.

'Veganin' is a compound of minimal doses of codeine phenacetin and acetyl salicylic acid. The synergistic effect of these drugs of related action provides safe analgesic, antipyretic and antispasmodic medication because the full force of the individual drug is obtained without its necessary manifestations. There is no likelihood of after effects or habit formation.

Composition: Each tablet 118 mg. codeine phenacetin, 32 mg. acetylsalicylic acid, 32 mg. phenacetin, 32 mg. codeine, 0.9 mg. caffeine, 100 mg. excipient.

## NEW TREATMENT FOR ASTHMA

Relatively free from the undesirable cardiovascular and other side effects of adrenaline injections, 'Neo-Epine', a recently developed homologue of adrenaline, possesses marked advantages in the treatment of bronchial asthma. It may be given subcutaneously or by oral spray. The drug has been found to be an effective substitute for adrenaline. Superior to ephedrine, it does not cause sleeplessness.

## 'NEO-EPINE'

ISOPROPYL-ADRENALINE SULPHATE

Each ampoule contains 1 mg. of the active ingredient. The ampoules are sealed under vacuum and are suitable for use in the treatment of asthma.

## INTRODUCING:

# Nitrogen Mustard Hydrochloride- Boots

A POWERFUL cytotoxic agent which in carefully controlled dosage acts selectively against cells showing increased proliferative activity. Clinical trials have shown that the intravenous injection of Nitrogen Mustard Hydrochloride will reduce the tumour masses in cases of Hodgkin's disease that have become resistant to X-rays, and will bring about a fall in the white cell count in some cases of chronic myelogenous leukaemia. It is also of value in the reticulososes and in some cases of lymphosarcoma.

## A Healthy Community

It is a matter of universal concern, now more than ever, to ensure that the health of the nation should be maintained. Considerable importance is therefore attached to the welfare of the rising generation and, for this reason, expectant and nursing mothers and children are recognised as priority groups, especially where their nutritional needs are concerned.

Marmite supplies essential vitamins of the B. complex and in addition it contains a useful anti-anaemic factor of particular value in nutritional macrocytic anaemia. It is prescribed extensively in maternity and child welfare work and in private and hospital practice.

## MARMITE yeast extract

## VETERINARY SURGEONS BILL

The Veterinary Surgeons Bill which originated in the House of Lords and had been amended in a Standing Committee of the House of Commons, passed through the Report Stage in that House on July 9 after the Speaker had ruled out an amendment dealing with the docking of tails.

Mr GEORGE BROWN for the Ministry of Agriculture then moved that the Bill be read a third time. He said that its two purposes—the extension of facilities for veterinary education and the control of unqualified practice met with approval on all sides of the House. He mentioned two matters which had been raised during the committee stage. One concerned the position of aliens. The Royal College already had power in suitable cases to register practitioners holding recognized foreign diplomas so no new powers appeared to be required. The second question concerned partnerships between an unqualified man and a veterinary surgeon. He understood that it would not be proper for a registered veterinary surgeon to enter into partnership with an unregistered person and that a by-law of the Royal College prohibited it. This ban did not apply to existing practitioners registered under the Act of 1881. Persons registered in the *Supplementary Register* would similarly have a status in the profession. What should constitute professional conduct in matters such as this was best left to the governing body of the profession to decide.

Sir HENRY MORRIS JONES said the Bill completed the process of regularizing the professions dealing with human beings and animals. He remembered the days in medicine when doctors had unqualified assistants. Eventually they became registered and made very fine medical practitioners. Under another measure unqualified dentists were allowed to become registered. Now Parliament was doing the same thing for the unqualified veterinary surgeon.

Sir IAN FRASER repeated a question raised in Committee. Was it right that therapists, masseurs, and bone setters should not be permitted to practise on animals? He said that whereas he could call in one of these to treat his daughter's ankle he could not call in any of them to treat his horse's fetlock.

Sir THOMAS DUGGALL said the Minister had satisfied the Committee that he could make an Order under Clause 5 whereby treatment by physiotherapy as well as electrical treatment could be given for animals particularly horses.

Mr GEORGE BROWN intervening towards the end of the debate said nothing would be more foolish than to encourage young men to go through a long and expensive training if they could not be sure of a position when they had completed it. The Government aimed to produce 220 new entrants a year, but there was nothing in the Bill to limit the output at that figure. Any university was authorized to give veterinary courses as soon as it was clear that they had all the facilities and they knew that it would be wise to increase the total number of entrants into the profession. With regard to physiotherapists, the Government would consider sympathetically what sort of an order it could make, but the point could not arise for the first year after the passage of the Bill. The only ban contemplated was a ban on diagnosis, not on treatment.

The Bill was then read a third time.

## PROPRIETARY MEDICINES

Mr STAFFORD on July 12 raised the subject of the price of proprietary medicines and asked whether it was possible to obtain a declaration from the Minister of Health on the proprietary medicine industry now that the National Health Act was in operation. He said this industry whose capital was probably more than £100,000,000 and which made some of its profit out of human credulity and suffering was almost uncontrolled. It seemed ludicrous to spend £160,000,000 a year on the health services while newspapers and handbills all over the country carried inducements to persuade people not to take full advantage of the scheme. Before the war the advertisement costs of this industry were estimated at just under £300,000,000 and he had no reason to suppose that they were less to-day. Mr STAFFORD explained that he did not speak of proprietary preparations advertised in medical and scientific journals but of those advertised direct to the public. He recognized that some well-known remedies could be used without causing great harm to the individual but the Ministry of Health ought to realize that proprietary medicines by encouraging self-medication, might prevent the best use being made of the Health Service. One of his acquaintances had just produced a study of 120 well-advertised proprietary medicines but owing to the law of libel he could not find a publisher and when he did find one prepared to take the risk of publishing he could not find a printer prepared to take the risk of printing it.

Dr HADEN GUEST Ask the B.M.A. They have done it once

Mr STAFFORD said he was not suggesting legislation, but in the public interest attention should be drawn to the discrepancy between the cost of the ingredients of these preparations and the price at which they were sold. One of the advantages of the Medicine and Pharmacy Act 1941 was that the contents now had to be disclosed on the label of the bottle but these formulae were in extremely small print which many people could not read and often in Latin which many people did not understand.

## Relevant Statutes

Mr JOHN EDWARDS replying for the Minister of Health said a large number of statutes governed articles which were proprietary medicines. These included the Venereal Diseases Act 1917 the Dangerous Drugs Acts 1920-2 the Therapeutic Substances Act 1925 and the Pharmacy and Poisons Act 1935. The Food and Drugs Act 1938 made it illegal to sell a drug which had a label falsely describing it or otherwise calculated to mislead as to the nature of the substance or its quality. The Cancer Act 1939 prohibited advertisements of cure of cancer and the Pharmacy and Medicines Act 1941 altogether prohibited advertisements for the cure of such diseases as Bright's disease, tuberculosis and the like. The same Act required full disclosure on the label of the active ingredients of all the medicines. Finally the Penicillin Act 1947 dealt with the whole range of penicillin products. This control was not concerned with the price at which these things were sold and there was no way under present legislation by which they could be controlled.

Voluntary efforts had been made by some of the people directly concerned to keep extravagant advertising in check. Bodies like the Proprietary Association of Great Britain and the Advertising Association had drawn up a tightened code governing what should be put on the bottles and in advertisements. Unfortunately that code did not bind those who were not in the Associations. Yet one in the country was now entitled to a comprehensive health service and he believed that on providing for everyone the medicines which the doctor considered necessary there would be less inducement to buy medicines which made no real sense. Doctors for the most part would not prescribe medicines of the kind mentioned and if they were to do so their colleagues on the local medical committee would soon point them out. In so far as the medicines were costly in relation to the cost of the ingredients then it was for the public to be educated and to watch the service free of charge under the Health Service against the doubtful value of self-medication. He hoped that the efforts which some of the trade themselves were making would go at any rate some way towards meeting the situation.

## Food and Health

Opening a debate on the minutes of the Ministry of Food on July 12 Mr J. C. S. RIM pointed out that the Economy Survey for 1945 showed a fall in the consumption of a number of commodities and demonstrated that the food available during the year had diminished by 200 calories per head per day on the average. He recognized that many quite properly got more than the average through canteens, school meals and extra rations but a great many got less. He suggested to Mr. Strachey that the time had come when he should re-examine his method of deciding who was to get extra allocations of food. He thought that the Ministry of Food relied too much on statistics. He hoped that as soon as harvest prospects became assured Mr. Strachey would announce that he was going to lower the extraction rate of flour. He also urged him to make much more sugar available in an early date.

Mr. STAFFORD said the House could rely on him to be rid of bread rationing at the earliest possible moment. The Ministry would like to lower the extraction rate further and if it could not be lowered by 5% it would be well worth while to lower it by 2%. It was true that last autumn the nutritional prospect for the first six months of 1948 had been dark indeed. But the Ministry took active measures to fill the gap and were helped by favourable weather. The calorie level remained almost exactly 2,600 and did not fall below 2,700 as the Ministry had feared. He would not say that 2,600 calories was too much. In the opinion of the Ministry's scientific and nutritional advisers it was only just sufficient. He referred to the welfare services which the Ministry continued to run and said 52% of all school children now received school meals as against 4% before the war. There was an imperative need for the fullest possible sharing of foodstuffs. He cited a tribute to the condition of British children given last month by Professor Henri Bonnet, Director of the French Red Cross. Professor Bonnet said that in ten years England would have a generation

of young men and women superior to those of any other European country. The excellent physical condition of these children was due to their feeding. Their diet was perfectly balanced. Mr Strachey observed that research work had gone on for over a year in Manchuria and Malaya on the production of edible oil from rubber seeds. It would be most valuable if this could be developed. From the East African plantations of ground-nuts there would be a commercial product in the spring or early summer of 1949. He believed the fall in the price of basic foodstuffs would continue after the harvest.

Replying to the subsequent debate, Dr SUMMERSKILL said the people of the United Kingdom consumed 50% more milk than before the war, and the demand continued. In reply to a call for jam to be de rationed she said this would make great demands for sugar and therefore the Ministry had to refuse. The Ministry was considering how it could dispose of the glut of plums and would probably make an announcement soon.

### Physicians Approved by Bishops

The Joint Committee of the House of Lords and of the House of Commons appointed to consider all Consolidation Bills in the present session recently heard evidence given by Sir Cecil Carr counsel to the Speaker, on the Statute Law Revision Bill. The Bill proposes, among many other repeals and revisions, the repeal of an Act of Henry VIII which states that physicians and surgeons are not to practise in London unless they are examined and approved by the Bishop of London or the Dean of St Pauls and not elsewhere unless they are approved by the bishop or the vicar-general of the diocese. It was in 1310 that a Continental Council gave the bishops authority over medical practice, but this control was subsequently found inadequate and the Act of Henry VIII was passed to deal with this situation. It was designed to restrict unqualified practice, but at the present time it would prohibit all qualified practitioners from practice in the absence of clerical approval, which none of them has obtained. The Act is obsolete, and all the authorities concerned, the Royal Colleges, the General Medical Council, the Bishop of London, the Dean of St Pauls, the Ministry of Health, the Privy Council and the Church Assembly Legal Board have been consulted and agree that it should be repealed.

Under the same Bill the repeal is proposed of another Act which concerns physicians practising in London and which directs that certain offenders may be committed by the President of the College of Physicians to be duly kept by jailors of any prison in London except the Tower. Another Act the repeal of which is recommended is the Lying in Hospitals Act of 1773. Sections 10 and 11 of this Act state that owners or masters of hospitals must take pregnant women before admission to be examined before a magistrate as to whether they are married or single.

### Tuberculous School-teachers

On July 1 Mr ANTHONY GREENWOOD asked whether Mr Tomlinson had reminded education authorities of the standing instructions issued by the Ministry of Health and his department that a teacher found to be suffering from active tuberculosis should be suspended from teaching. Mr Greenwood further asked the Minister whether he had considered the desirability of making it compulsory for all teachers to have a regular medical overhaul in order to ensure that they were not carriers of tuberculosis.

Mr TOMLINSON said a memorandum had been issued reminding education authorities of the action to be taken when a teacher was found to be suffering from active tuberculosis. The memorandum did not require teachers to be medically examined at regular intervals after their entry into teaching service.

**Cracked Crockery**—Mr STRACHEY said on July 5 that infection could be spread by any crockery which had not been properly cleaned after use, but that his medical advisers took the view that cracks did not materially enhance the danger. It was of the utmost importance that caterers should protect their customers by thorough cleansing and, where possible, sterilization.

**Medresco Hearing aid**—Mr BEVAN said on July 8 that supplies of the magnetic type of Medresco hearing aid were sent to four hospitals in England and Wales in time for them to begin operating the scheme on July 5. Supplies of the crystal type should begin to be available at the end of this month. The number of distribution centres would be increased to about 25 as soon as possible.

**Cars for Midwives**—Mr ODEY inquired on July 1 what steps had been taken to provide midwives, nurses, and health visitors in rural districts with motor transport when the new Health Service came into operation. Mr BEVAN said supply was still difficult, but any chances of improvement were being explored with the motor industry.

† Deaths from measles and scarlet fever for England and Wales (London administrative county) will no longer be published

‡ Includes primary form for England and Wales (London administrative county) and Northern Ireland

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales (London administrative county) are combined

|| Includes puerperal fever for England and Wales and Eire

## EPIDEMIOLOGICAL NOTES

## Typhus in County Tyrone

Two cases of typhus fever have been notified in County Tyrone. On July 19 the Northern Ireland Ministry of Health stated that the two patients were children from the Finton district and had been playing with the children of a gipsy tinkler colony. Steps are being taken to disinfect all gipsy and tinkler encampments in the district.

## Poliomyelitis

Reports from B U P correspondents show that outbreaks of poliomyelitis are in progress in certain areas of the United States, while Europe on the whole is experiencing fewer cases than usual. The worst-affected area in the United States is North Carolina. More than 500 cases have been reported in the State so far. In Europe there are reports of increases in incidence from Stockholm and Berlin, but other cities report fewer cases than in previous years. Sweden reports 103 cases from Jan 1 to June 15 this year, as compared with 49 cases in the same period of last year. In the second half of last year a total of 1,454 cases were reported in Sweden.

German and Allied health authorities in Berlin recorded 34 cases, 3 of them fatal, in April and May, compared with only one case over the same period last year. During the second half of 1947 a total of 339 cases were reported in Berlin with 12 deaths.

Fewer cases than in previous years are predicted for the whole of Belgium this year by Ministry of Health officials in Brussels. In 1945 there were 960 cases in Belgium, but this had dropped to 260 cases by last year. The pre-war average was between 80 and 100 cases each year. Switzerland reports a similar decline, from 1,793 cases in 1944 to 932 cases in 1946 and 755 cases in 1947. Only 41 cases had been reported up to the middle of May, 1948, as compared with 56 in the same period last year. Holland's worst year was 1943, when 1,931 cases were reported. The number had dropped to 693 by last year although this is still high when compared with the pre-war average of some 300 cases a year.

## Discussion of Table

In England and Wales the only variations of any size in the returns of infectious diseases were decreases in measles 1,584 and scarlet fever 117 and an increase of 104 in the incidence of whooping-cough.

The largest decreases in the notifications of measles were London 200, Durham 185, Warwickshire 168, Flint 141, Staffordshire 131, Lancashire 131, Cheshire 116, and Middlesex 111. The largest increases were Yorkshire West Riding 53, Sussex 47, and Caernarvonshire 47. The only variation of any size in the local returns of scarlet fever was a decrease of 50 in Lancashire. The largest increase in the incidence of whooping-cough was 36 in Norfolk. An increase of 9 in the notifications of diphtheria in Lancashire was the chief feature of the returns of this disease. An outbreak of dysentery affecting 11 persons was notified from Sussex, Chislehurst R D. The other large centres of infection were Yorkshire West Riding 11, London 9, Lancashire 8 and Norfolk 8.

The notifications of acute poliomyelitis increased by 9. This is the third consecutive week showing a small increase. There seems a possibility that the course of this disease will be similar to that of cerebrospinal fever in the early war years and that we may expect a high seasonal rise in the autumn. During the week multiple cases were notified in Bedfordshire, Bedford MB 4, Leicestershire, Leicester CB 4, Sussex, Arundel MB 2, Middlesex, Enfield UD 2, Staffordshire Walsall CB 2, Warwickshire, Birmingham CB 2, Yorkshire East Riding Kingston-upon-Hull 2. Other counties with multiple cases were London 3, Derbyshire 2 and Lancashire 2.

In Scotland a decline was recorded in the incidence of most infectious diseases. There were falls in the incidence of measles 45, scarlet fever 41, and whooping-cough 20. The notifications of dysentery in Edinburgh rose from 4 to 10. In the eastern area there was a rise of 18 in the notifications of scarlet fever.

In Eire decreases were recorded in the totals for diarrhoea and enteritis 34, whooping-cough 17, and measles 12, while increases were reported in the incidence of scarlet fever 14 and diphtheria 5. A further 27 cases of measles were notified from the outbreak in Galway, Loughrea R D.

In Northern Ireland the largest variations in the returns were a decrease of 13 for scarlet fever and an increase of 6 for diphtheria.

## Week Ending July 10

The notifications of infectious diseases in England and Wales during the week included scarlet fever 1,658, whooping-cough 3,075, diphtheria 150, measles 8,837, acute pneumonia 340, cerebrospinal fever 24, acute poliomyelitis 23, dysentery 56, paratyphoid 6 and typhoid 5.

the oval window, or the vestibular nerve may be cut. Tetraethyl-ammonium chloride is used to reduce high blood pressure but so far as the writer knows, has no place in the diagnosis and treatment of Ménière's syndrome.

### Sprue and Malignant Disease

**Q**—Does sprue predispose to malignant disease? If a patient with sprue developed a carcinoma of the bowel laparotomy could not be undertaken because of the weakness and emaciation and death might be wrongly attributed to the sprue.

**A**—There is no reliable evidence that sprue predisposes to malignant disease. With adequate treatment most cases of sprue respond rapidly and satisfactorily enough to permit exploratory operation where indicated.

### Gonorrhoea, Syphilis, and Penicillin

**Q**—A patient who was successfully treated with penicillin for gonorrhoea four months ago has developed a primary sore in which *Spirochaeta pallida* has been found. The Wassermann reaction is negative. (a) What is the prognosis in these cases? Does the fact that penicillin has been given make cure more difficult? (b) The patient had unprotected intercourse with his wife about a month before the first sign of the sore but not after that. Is there any danger that she might have been infected on this occasion which was presumably during the incubation period?

**A**—(a) The prognosis is good provided adequate treatment is administered without delay. There is no reason to suppose that the syphilis will be more difficult to cure because the patient was treated with penicillin for gonorrhoea. (b) There is a risk that the patient may have infected his wife, but it is small, it would therefore be wise to keep her under observation for at least three months, with periodical clinical and serological examinations.

### Retardation of Growth

**Q**—(a) Has an anti-growth hormone definitely been isolated? (b) What is the substance that might be called the opposite number of the anterior pituitary growth hormone? (c) Can such substance be utilized to prevent the growth of cells in certain organs of the human body to the exclusion of cells in other organs of the body?

**A**—(a) No. (b) There is no such substance, but experimentally the giving of certain hormones, such as oestrogens, will inhibit initial secretion of the pituitary gonadotrophic hormone and subsequently all other hormones, including the growth hormone. Thus Zondek produced dwarfism in mice so treated together with hypogonadism, and the pituitary gland showed loss of the granules of both the eosinophil and the basophil cells, and sometimes a large chromophobe adenoma was also produced. Clinically it is difficult to stop somatic growth or to inhibit the development of acromegaly by such methods, but relative success in the latter is sometimes obtained. (c) No.

### Keeping Qualities of Aspirin

**Q**—Does aspirin in a mixture deteriorate appreciably? Is it best to prescribe aspirin in tablet form?

**A**—Aspirin is a somewhat unstable chemical, hydrolysing in the presence of water into free salicylic and acetic acids. In mixture form it decomposes fairly rapidly, and even in powder and tablet form it cannot be relied upon to keep for prolonged periods, particularly in a moist atmosphere. The odour of acetic acid on opening the container is an indication of decomposition, and if this odour is strong one may suspect very appreciable deterioration.

### Acute Cystitis

**Q**—What is the prognosis in a man of 70 with some prostatic enlargement who had an acute cystitis twelve years ago and a recurrence two months ago? The urine was freed from the infecting organisms—*Bact. coli* and *Str. faecalis*—after a course of sulphadiazine. Can treatment with sulphonamides be continued with impunity and are further relapses likely?

**A**—It is very difficult to get rid of a urinary infection in the presence of residual urine, and in this case there is likely to be

residual urine. The best method of treatment is either by means of calcium mandelate or by the use of the sulphonamides. As a sterile urine was temporarily obtained after taking sulphadiazine there is no reason why this should not be repeated. Sulphamezathine is probably even less toxic than sulphadiazine, but if either of these preparations is taken in moderate doses and with plenty of fluids for only a week no harm will be done. Occasional relapses are likely, but in time a higher resistance to the infecting organisms may be developed. Provided the residual urine does not increase, the outlook is satisfactory.

### Nerve Deafness and Syphilis

**Q**—What is the best treatment for a patient aged 65 with marked arteriosclerosis of the limbs who is now rapidly developing nerve deafness? He has positive Wassermann and Kahn reactions and has had a full course of penicillin without effect but no other antisyphilitic treatment. The old specific trouble has been quiescent for years apparently and the positive Wassermann reaction was only accidentally discovered. Would trypanamide and bismuth arrest the nerve deafness?

**A**—It would be wise to obtain the opinion of a neurologist on whether the nerve deafness is due to syphilis which seems at least problematical. The full effects of penicillin in certain forms of syphilis are often not apparent for some months. Assuming the patient has had at least five mega units, further antisyphilitic treatment is not indicated until several months have elapsed. If the condition has not improved by then injections of oil soluble bismuth, given twice weekly, might be worth trying. Trypanamide should not be employed. In view of the condition and age of the patient the prognosis is far from good.

## NOTES AND COMMENTS

**Loss of Weight after Hysterectomy**—Dr A. RUSSELL (Edinburgh) writes: I trust you will permit a suggestion concerning the answer to the query describing loss of weight after hysterectomy ("Any Questions?" July 10, p. 117). The slowly progressive loss of weight with wasting apparently confined to face, upper limbs, and trunk—the lower limbs remaining "quite muscular"—might well suggest a progressive lipodystrophy. You will agree that this condition may arise in adult life, principally in females, and may be associated with atrophic lesions of the hypophysis, ovarian lesions, etc., so that the pathology implied in the question may not be unrelated. The concentration of the wasting in the face together with the unimpaired general condition, would appear to give added support to the diagnosis suggested.

### Corrections

In our report of a meeting of the combined Sections of Child Health and Radiology on Friday, July 2 (*Journal* July 17, p. 162) Professor Wilfrid Gaisford (Manchester) was reported as saying "not all malignant cases were curable." This should have read "not all cases were fatal which is quite commonly assumed." The reference to a raised basal metabolic rate in cases of medulloblastoma was also incorrect and should have read "Topper had found that in all intracranial tumours, whether benign or malignant, the basal metabolic rate was lowered, whereas in all malignant tumours in other parts of the body it was raised." The phrase "staggering was a common first symptom" should have been deleted, and Wilms's tumours are, of course, radiosensitive. "The inguinal glands were enlarged" should have read "were not enlarged."

We regret that in the letter from Sir Frederick Menzies (July 17, p. 171) an error occurred in the printing of the first line of the second paragraph. It should read "Not one of these men ever received any public recognition of their great services to London."

There was a misprint in the report of the visit of the Section of Pathology to the Strangeways Research Laboratory at Cambridge (July 17, p. 160). Reference was made to an important demonstration of the histological assessment of the radiation treatment of cancer by "Dr A. Glausmann and Dr F. G. Spears." This should have read "Dr A. Glucksmann."

# SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY JULY 24 1948

## COMPENSATION FOR THE LOSS OF GOODWILL

### SUBMISSION OF CLAIMS

*The following Memorandum is being sent by the Ministry of Health to local executive councils together with a copy of the National Health Service (Medical Practitioners Compensation) Regulations 1948 (No 1506). We reproduce the Regulations after the Memorandum.*

1 A copy of the regulations which have been made after consultation with representatives of the medical profession is enclosed together with a form on which to claim compensation for the loss of the right to sell the goodwill of a medical practice. The submission and assessment of claims is governed by the regulations, to which reference should be made, but attention is drawn to the following matters—

2 *Doctors eligible to claim*—Regulation 5—The doctors entitled to claim are those who were engaged as principals in general medical practice immediately before July 5, 1948, and whose names were entered on July 5, 1948 on the medical list of an executive council as practitioners undertaking to provide general medical services (or maternity medical services) under the Act.

A doctor will not be entitled to compensation if he has acquired the practice of a doctor who retired or died between Nov 6 1946, and July 5, 1948, and in respect of whose practice a claim for compensation is paid by virtue of Section 37 of the Act. This disqualification will not apply to an acquisition of a practice by purchase.

3 *Submission of claims*—Regulation 3 (3)—Where the claim is based on the doctor's own gross receipts (and not on the gross receipts on which the purchase price paid for the goodwill was based) a certificate of a qualified accountant or a certificate of the local Inspector of Taxes is necessary, and this should first be obtained. The claim should then be sent to the Ministry at the address shown on the form.

It is important that the claim should be made promptly, since it will not be possible to allocate the total amount of compensation available until a decision has been reached on all the claims submitted. For this reason Oct 31 has been fixed as the last day for sending in claims and only in special circumstances will a claim sent after that date, but before April 30, 1949, be admitted.

Doctors on the list of more than one executive council may receive a copy of the claim form from each council, but only one claim form should be completed.

4 *Assessment of the annual value of a practice*—Regulation 7—In general, the annual value of a doctor's practice will be taken as the average gross yearly receipts of his practice calculated by reference to the last two accounting years or, in the case of a doctor in a partnership, his share as at July 5 of the average gross yearly receipts of the partnership calculated in the same way.

The Minister will determine the annual value of each doctor's practice and in difficult cases he will have the advice of the committee of five, referred to in Regulation 8. Three of the members of this committee will be medical practitioners.

Each doctor will be informed as soon as possible of the amount determined by the Minister to be the annual value of his practice for compensation purposes and it will then be open to him if he is aggrieved by the decision, to apply to the Minister for his case to go to arbitration (Regulation 11).

5 *Determination of the amount of compensation payable*—Regulation 12—The total sum available for distribution to doctors in Great Britain will be £66 000 000 (provided the number of practitioners on the medical lists of executive councils at July 5, 1948, is not less than 17,700).

Each doctor entitled to compensation under the Act will receive a share of the total in the proportion that the annual value of his practice bears to the aggregate annual value of the practices of all the doctors so entitled. It follows that until the annual values of all practices have been assessed it will not be possible to determine the amount of compensation payable to any doctor. Individual notifications will be made as soon as the calculations are complete.

6 *Time of payment*—Regulation 13—After the amount of the compensation payable to each doctor has been determined payment of the amount due will be made on retirement (as defined in the regulations) or earlier death.

There is however provision for an advance payment on account where hardship would otherwise arise. Doctors claiming early payment are asked to submit with their application details of the grounds on which it is made (Regulation 13 (2) (d)). If hardship is claimed because of heavy charges in respect of loans raised for the purchase of the practice particulars should be given of these loans for example amount outstanding, the rate of interest and the amount and date of the repayments of principal. This information as well as that submitted in support of the claim for compensation will be treated as confidential. Application for early payment on grounds of hardship may be made at any time.

7 *Interest*—Regulation 14—Interest at the rate of 2½% (less tax) will be paid until the time when the compensation is paid. Payment of interest cannot however be made until each doctor's share of compensation has been determined and the first payment covering the period from July 5 1948 will be made on July 5 1949. Payment will be made at half-yearly intervals thereafter.

8 *Partnerships*—Doctors will probably be aware that a legal committee is at present investigating the special position of partnerships under the National Health Service Act and will advise the Minister in due course. Further regulations or an amending Act will be necessary in the light of the committee's recommendations.

It will not therefore be possible finally to allocate compensation between partners under these regulations, but the value of each partner's share of the practice will be assessed and the claim form should be completed and sent in without waiting for the findings of the committee.

## THE NATIONAL HEALTH SERVICE (MEDICAL PRACTICES COMPENSATION) REGULATIONS, 1948 (No 1506)

The Minister of Health, in exercise of his powers under sections 36 and 74 of the National Health Service Act, 1946, and of all other powers enabling him in that behalf, hereby makes the following regulations —

### PART I

#### General

1 These regulations may be cited as the National Health Service (Medical Practices Compensation) Regulations, 1948, and shall come into operation on the 5th day of July, 1948

2 (1) In these regulations, unless the context otherwise requires, the following expressions have the respective meanings hereby assigned to them —

‘the Act’ means the National Health Service Act, 1946, the appointed day” means the fifth day of July, 1948,

‘accounting year’ in relation to a medical practice means the period of twelve months for which the accounts of the practitioner engaged in that practice are made up,

‘medical list’ means the list prepared by an Executive Council of medical practitioners undertaking to provide general medical services,

‘practitioner’ means a registered medical practitioner,

‘aggregate amount of compensation’ means the aggregate amount of compensation payable to practitioners in England and Wales under section 36 of the Act,

‘qualified accountant’ means a person who is a member of one or more of the following bodies —

The Institute of Chartered Accountants in England and Wales

The Society of Incorporated Accountants and Auditors,

The Society of Accountants in Edinburgh,

The Institute of Accountants and Actuaries in Glasgow

The Society of Accountants in Aberdeen,

The Institute of Chartered Accountants in Ireland,

The Association of Certified and Corporate Accountants Limited

(2) For the purposes of these regulations references to the goodwill of a medical practice shall, unless the context otherwise requires, in relation to a practitioner practising in partnership be construed as referring to his share of the goodwill of the partnership practice

(3) The Interpretation Act, 1889, applies to the interpretation of these regulations as it applies to the interpretation of an Act of Parliament

### PART II

#### Submission of Claims, Determination of Loss, and Payment of Compensation

3 (1) A practitioner whose name is entered on the appointed day on a medical list and who claims to be entitled to compensation under section 36 of the Act in respect of any loss suffered by him by reason that he is, or will be, unable to sell the goodwill, or any part of the goodwill of his medical practice by virtue of section 35 of the Act shall make application to the Minister in the form set out in the schedule to these regulations or in a form to the like effect. If any such practitioner dies without having submitted a claim for compensation the application shall be made by the personal representative of that practitioner

(2) Where a practitioner or the personal representative of a practitioner has obtained a certificate from the Medical Practices Committee certifying that the conditions of section 37 of the Act have been satisfied in relation to that practitioner and to his practice, the practitioner or the personal representative, as the case may be, shall be entitled to apply for compensation as if the practitioner were entitled to do so under paragraph (1) of this regulation

(3) The form of application shall be duly completed by the applicant and delivered or sent by post to the Minister on or before the thirty-first day of October, 1948. Provided that, where the Minister is satisfied that by reason of unavoidable delay in the appointment of the personal representative of a deceased practitioner or in obtaining a certificate from the Medical Practices Committee under section 37 of the Act or for any other reason it is not or has not been practicable to submit an application by the thirty-first day of October, 1948, the Minister may allow such further period not exceeding six months for the submission of the claim as appears to him to be reasonable

#### Medical Practitioners in Partnership

4 The provisions of the succeeding regulations shall be subject, so far as they affect medical practitioners practising in partnership, to any provisions made hereafter either by further regulations under section 36 of the Act or by or under any Act amending the Act

#### Determination of Loss

5 Subject to the provisions of these regulations, every medical practitioner engaged immediately before the appointed day as a principal in general medical practice whose name is entered on the appointed day on a medical list, and every practitioner in respect of whom and of whose practice a claim for compensation can be made in accordance with paragraph (2) of regulation 3, shall be deemed to have suffered loss, and he or his estate, as the case may be, shall be entitled to compensation. Provided that a practitioner who on the appointed day would have the right to sell, but for the provisions of the Act, the goodwill or any part of the goodwill of a medical practice in respect of which a claim has been made under section 37 of the Act shall not, if compensation is payable in respect of that claim, be deemed to have suffered loss in respect of that goodwill or any part of it

#### Extent of Loss

6 The extent of the loss of a medical practitioner or the personal representative of a medical practitioner who is entitled to compensation under the last preceding regulation shall be determined in accordance with the following provisions of these regulations

#### Annual Loss

7 (1) There shall be ascertained the annual value of the goodwill of the practice of each practitioner who has claimed compensation or in respect of whom and of whose practice a claim for compensation has been made. Such annual value is hereinafter referred to as “the annual loss”

(2) For the purpose of these regulations “the annual loss means —

(a) in respect of the practice (not being a partnership practice) in which the practitioner was engaged on the appointed day, the average gross yearly receipts of that practice, as certified by a qualified accountant, calculated by reference to the last two accounting years immediately preceding the appointed day

(b) in respect of a partnership practice in which the practitioner was engaged on the appointed day, such proportion of the average gross yearly receipts of that practice, as certified by a qualified accountant, calculated by reference to the last two accounting years immediately preceding the appointed day, as the share of the goodwill of the partnership practice held by him on that day bears to the whole goodwill of the partnership practice,

(c) in respect of a practice to which section 37 of the Act applies, the average gross yearly receipts of that practice, as certified by a qualified accountant, calculated by reference to the last two accounting years immediately preceding the date of the retirement from practice or death of the practitioner

Provided that —(i) in the case of the goodwill of a practice acquired by purchase after the beginning of the first of the two accounting years by reference to which the average gross yearly receipts of the practice are, under the preceding provisions of the regulation, to be calculated, the annual loss means the average gross yearly receipts of the practice as estimated for the purpose of the purchase,

(ii) in the case of any claim referred to the Committee appointed under the next succeeding regulation the Committee shall fix as the annual loss in respect of the practice such sum as they estimate fair to represent the average gross yearly receipts of the practice

(3) A practitioner or the personal representative of a practitioner submitting a claim for compensation under these regulations may, if he so elects, instead of having the gross receipts of the practice certified by a qualified accountant, submit with his claim a certificate in such form as may be agreed between the Minister and the Commissioners of Inland Revenue, signed by the Inspector of Taxes, whom income tax returns in respect of that practice have been submitted

(4) In calculating the average gross yearly receipts of a practice for the purposes of paragraph (2) of this regulation no account shall be taken of fees or remuneration received for or in respect of the holding of any appointment or of any other fees or remuneration which would not normally be taken into account in assessing the value of the goodwill of a general medical practice for the purpose of the sale thereof

#### Practices Compensation Committee

8 (1) There shall be constituted a committee to be called the Practices Compensation Committee (hereinafter referred to as “the Committee”)

(2) The Committee shall consist of a chairman and four other members. Three of the five members shall be medical practitioners

(3) The chairman and members shall be appointed by the Minister after consultation with such organization as the Minister may recognize as representing the medical profession

(4) The Minister shall appoint a Secretary to the Committee and such organization as the Minister may recognize as representing the medical profession may also appoint a Secretary to the Committee who shall act jointly with the Secretary appointed by the Minister. The Minister may also provide the services of such other officers as the Committee may require

#### Claims Submitted to Committee

9 (1) The Minister shall refer to the Committee all claims for compensation submitted in accordance with Regulation 3 which in his opinion should be considered by the Committee

(2) It shall be the duty of the Committee to consider the claims referred to them and to report their findings to the Minister

#### Decisions on Claims

10 The Minister, after considering each claim for compensation and if the claim has been referred to the Committee, the findings of the Committee, shall notify the claimant or his personal representative of the annual loss as determined by the Minister for the purpose of calculating compensation under these regulations

#### Arbitration

11 (1) Any claimant or his personal representative who is aggrieved by the decision of the Minister under the last preceding regulation may within fourteen days of the date of the notice given under that regulation apply to have the annual loss determined by arbitration

(2) Any such application shall be sent to the Minister who shall thereupon refer the matter to the arbitration of a single arbitrator sitting with two assessors. The arbitrator and assessors shall be appointed by the Minister after consultation with such organization as the Minister may recognize as representing the medical profession

#### Distribution of Aggregate Amount of Compensation

12 (1) For the purpose of calculating the distribution of the aggregate amount of compensation among persons who under these regulations are deemed to have suffered loss by reason of the matters referred to in regulation 3 there shall be calculated the aggregate of all annual losses determined in accordance with these regulations. The aggregate of such losses is hereinafter referred to as the aggregate annual loss

(2) Subject as is otherwise provided in these regulations there shall be payable out of the aggregate amount of compensation by way of compensation—

(a) to a practitioner practising otherwise than in partnership, or the estate of such a practitioner, who is entitled to compensation, such proportion of the aggregate amount of compensation as the annual loss determined to have been suffered by him or his estate on the appointed day bears to the aggregate annual loss,

(b) to a practitioner practising in partnership, or the estate of such a practitioner, who is entitled to compensation, such sum as may be determined by or under regulations made hereafter under section 36 of the Act or by or under any Act amending the Act

(3) A practitioner or the personal representative of a practitioner to whom compensation has become payable under the last preceding paragraph shall be notified by the Minister of the amount of compensation so payable

#### Payment of Compensation

13 (1) Subject as hereinafter provided, the compensation payable to a practitioner or the estate of a practitioner under the last preceding regulation shall be paid to the practitioner or his personal representative—

(a) in the case of a practitioner to whom and to whose practice section 37 of the Act applies as soon as may be after the amount of compensation so payable has been ascertained,

(b) in any other case, on the retirement from practice or death of the practitioner concerned, whichever shall first occur. Provided that if the amount of compensation payable has not then been ascertained payment shall be made as soon as may be after the amount due has been ascertained

(2) (a) A practitioner or the personal representative of a practitioner to whom and to whose practice Section 37 of the Act applies may, on the ground of hardship suffered or likely to be suffered by that practitioner or the persons entitled to his estate, at any time after the appointed day submit to the Minister a request for an advance payment on account of compensation in respect of which a claim has been made by that practitioner or his personal representative

(b) Where a practitioner whose name is entered on the appointed day on a medical list retires or dies without having received payment of compensation to which he is entitled, the practitioner or his personal representative may, notwithstanding that the compensation payable in respect of the goodwill of the practice of the practitioner has not been ascertained submit to the Minister on the ground of hardship suffered or likely to be suffered by him or the persons entitled to his estate a request for an advance payment on account of compensation in respect of which a claim has been made by the practitioner or his personal representative

(c) In any case not falling within sub paragraphs (a) or (b) of this paragraph a practitioner who claims to suffer hardship by reason of the non payment before the date of his retirement from practice or death of compensation to which he is entitled under these regulations may at any time submit to the Minister a request for immediate payment of the whole or any specified part of the compensation to which he is entitled or, if the amount of compensation payable to him has not been ascertained, for an advance payment on account thereof

(d) Any such request shall specify the grounds on which it is made and shall be supported by such written evidence as the practitioner or the personal representative of the practitioner considers necessary to justify the request

(e) The Minister shall forthwith on receiving any such request consider the request and if he is satisfied, after making such investigations as appear to him necessary, that the request or some part thereof should be met, shall pay on such terms as he thinks fit to the practitioner or the personal representative of the practitioner such sum as the Minister considers to be fair and reasonable having regard to the evidence before him

(3) For the purpose of paragraphs (1) (b) and (2) (b) and (c) of this regulation retirement from practice means retirement from practice as a medical practitioner providing general medical services under Part IV of the Act or under Part IV of the National Health Service (Scotland) Act, 1947

#### Interest on Amount of Compensation

14 (1) Subject as hereinafter provided there shall be paid out of moneys provided by Parliament interest at the rate of two and three quarters per cent per annum less tax at the standard rate on the compensation payable to a practitioner or his personal representative under these regulations, in respect of any period from the appointed day until the time when the compensation is paid

(2) Where an advance payment of compensation is made in pursuance of paragraph (2) of regulation 13, interest on the sum so paid shall no longer be payable

(3) The first payment of interest due under these regulations shall be paid on the fifth day of July, 1949, and thereafter interest shall be paid by half-yearly instalments on the fifth day of January and the fifth day of July in each year

The Schedule to the Regulations prescribes the form in which the medical practitioner, or in the case of his decease his representatives, may claim compensation under Section 36 of the Act

## National Health Service News

### REMUNERATION OF GENERAL MEDICAL PRACTITIONERS

Arrangements for the distribution of the Central Fund for the period July 5, 1948, to Sept 30, 1948, are now being discussed with the Ministry. First, an International Distribution Committee will determine the apportionment between England and Wales and Scotland. Secondly, Distribution Committees for England and Wales and Scotland, similar in constitution to the old N.H.I. Distribution Committees, will apportion the Fund to the various local executive councils. In order to do this executive councils will be instructed to count their Forms EC 1 as at July 31 so that they can be informed by Sept 1 how much money will be available for distribution in individual areas. Executive councils will then be able to distribute the money among the doctors on the council's medical list in proportion to the number of patients actually on the doctors' lists at the latest date possible. It is hoped that this will be not earlier than mid-August.

It is of vital importance that doctors should forward acceptances (Forms EC 1) to the local executive council without delay. Failure to do so may result in the area's share of the

rational pool' being disproportionate to the number who have signed on doctors lists

The following method of distribution will be adopted (A) The total civilian population in England and Wales and Scotland will be the Registrar-Generals estimate on June 30, 1948 (B) The Central Fund will consist of 95% of the estimated population multiplied by a quarter of the capitation fee (4s 6d) with a proportionate deduction for the first four days of July (C) From the amount arrived at by this calculation there will be deducted the amount set aside for mileage (approximately one quarter of £1,300,000) (D) The resulting sum will be divided between England and Wales on the one hand and Scotland on the other in proportion to the aggregate number of persons actually on doctors' lists, plus one-third of the estimated population not on doctors' lists in the two countries respectively (E) The share of England and Wales as ascertained in (D) will be apportioned between the executive councils in the same way as the total fund is divided between (a) England and Wales and (b) Scotland (F) The first charge on the share of each executive council as calculated in (E) will be the amount necessary to pay the appropriate proportion of any fixed annual payments to which doctors in the area of the council may be entitled. *The balance of the executive council's share will be distributed among the doctors on the council's medical list in proportion to the numbers of patients actually on the doctors' lists at the latest date in the period on which the council can make the necessary count. The numbers on the lists of doctors receiving a fixed annual payment will for this purpose be reduced by one-seventh.* (G) A proportion of the total share of England and Wales (probably 5%) will be withheld to provide for payments for temporary residents, emergency treatment, and anaesthetics, and to ensure so far as possible that payments to individual doctors in the next quarter will not vary too greatly from those for the current period

#### Basic Salary

Recent regulations indicate the conditions of payment of the fixed annual amount of £300. The payment will be made only to those doctors who elect to have it and who receive the consent of the executive council (after consultation with the local medical committee) or, on appeal, of the Minister. (When the fixed annual payment is made the capitation fees of those receiving it will be reduced by one-seventh.) Executive councils have been informed that the Minister considers that consent ought to be given in cases where there is reasonable justification for so doing. Such justification might exist in the case of a doctor who is starting a new practice, or working up a small one, the doctor who on account of age or ill-health is unable to do as much as he has done in the past (when it is necessary that his services should be given) or the rural doctor in a sparsely populated area who cannot attract a large list (though these last cases will normally be covered by an inducement payment). It is possible that in a few areas where the proportion of doctors to the population is at present unusually high the coming into operation of the National Health Service may result in a drop in doctors' incomes. Local executive councils have therefore been informed that consent should be given in any case where a doctor's income can be shown to have dropped substantially as a result of the new Service involving an element of hardship.

It is important that doctors should distinguish between the fixed annual payment (which comes out of the central "pool") and the special "inducements" fund of £400,000 (which is quite separate from the central "pool") for unattractive areas, abnormal difficulties of practice, etc. The distribution of this fund is now under discussion and it is hoped that payments will be made in the current quarter. Rural practitioners will of course look to this fund to assist them in their special difficulties.

#### Dispensing Capitation Fee

The Ministry proposes that doctors who elect to be paid for dispensing on the basis of an annual capitation fee should be remunerated as follows: (a) for drugs and appliances on the special list at the rates laid down in the drug tariff (i.e., as for chemists), (b) for the rest, at the rate of 6s 6d a dispensing patient. These terms have been accepted without prejudice to the findings of any inquiry initiated into the cost of dispensing by doctors in rural areas.

### Certification

The Ministry has issued the following circular to local executive councils

#### NATIONAL HEALTH SERVICE MEDICAL CERTIFICATES

The following list sets out the enactments under or for the purposes of which doctors may be asked to issue medical certificates by their patients or the legal representatives of a patient who has died. Under paragraph 7 (7) of Part I of the first schedule to the National Health Service (General and Pharmaceutical Services) Regulations, 1948, such certificates given by a doctor on a medical list to patients for whom he is responsible (or to their personal representatives) would be given without charge.

The list is prepared for the general guidance of medical practitioners. It is not necessarily exhaustive, and will be reconsidered when the Inter-Departmental Committee on Medical Certificates has reported.

Serial	Enactment	Purpose for which Certificate is Required
1	Disabled Persons (Employment) Act 1944	To register under the Act
2	(i) Road Haulage Wages Act 1938 (ii) Catering Wages Act 1943 Wages Councils Act 1945 Agricultural Wages (Regulation) Act 1924 to 1947	To prove sickness to obtain guaranteed weekly wage In support of an application for a permit to be employed at a sub-standard wage rate or to obtain guaranteed weekly remuneration or statutory holiday
3	Juries Act, 1922	To claim exemption from a requirement to sit on a jury
4	Elections and Jurors Act 1945	To claim facilities to vote by post at a parliamentary election
5	Births and Deaths Registration Acts 1836 to 1926	(a) To certify nature of illness and cause of death (b) To certify that a child was born dead in a case of stillbirth
6	Lunacy Act 1890	(a) To certify under Section 55 (8) of the Lunacy Act 1890 that detention of a person absent on trial is no longer necessary (b) To certify under Section 335 of the Lunacy Act 1890 that a person is incapable of managing his own affairs
7	(i) Reinstatement in Civil Employment Act 1944 (ii) Control of Employment (Directed Persons) Order, 1943 (iii) Defence Regulation 80B	To extend time for making application for reinstatement when prevented by illness In support of claim for changed employment or withdrawal of direction To certify fitness for type of direction
8	(i) Services and Mercantile Marine Disability Pensions Acts (ii) Personal Injuries (Emergency Provisions) Act 1939	(a) To assist in determining a claim to war pension or allowance (b) To enable proxy to draw pension
9	Under Defence Regulation 55 (a) Welfare Foods Order 1947 (b) Food Rationing (General Provisions) Order 1947 Milk (Control and Maximum Prices) Order 1947 (c) (i) Control of Rubber Tyres (No 9) Order 1946 (ii) Control of Leather (No 2) Order 1944 Control of Leather (No 5) Order 1944 (iii) Consumer Rationing Order 1947 (iv) Utility Furniture (Supply and Acquisition) Consolidation Order 1946 (v) Import of Goods (Control) Order 1940 (vi) Apparel and Textile Order 1942 (vii) Miscellaneous Textiles (Manufacture and Supply) Directions 1942	(a) To enable an expectant mother to obtain food benefit or day nurseries to get milk (b) To enable invalids to obtain special authorities for supplementary rationed food (c) To enable invalids expectant mothers and others to obtain special treatment with regard to goods which are the subject of government control (rationing or dockets, etc.)
10	Coal Distribution Order, 1943	To assist people with young children old people and invalid in obtaining additional supply of rationed fuels for heating purposes
11	Control of Motor Fuel Order 1947	To assist claimants for additional petrol allowances on medical grounds
12	National Insurance Act 1946 National Insurance (Industrial Injuries) Act 1946	To support a claim to benefit
13	National Health Service Act 1946	To assist a person in obtaining any of the services provided under the Act e.g. supplementary ophthalmic services
14	Family Allowances Act, 1945	To enable proxy to collect allowance
15	Education Act, 1944	As evidence that a child was prevented from attending school because of sickness

The Association has been asked to give evidence before the Departmental Committee appointed by the Government to review the whole problem of certification, and must therefore reserve its detailed comments on the above provisional list until later. Immediate representations are being made, however, on Serial 15 to clarify its intention. It is submitted that a doctor is obliged to issue a certificate under the 1944 Education Act only where the parents are summoned for the child's non-attendance at school and medical evidence is required to support the parents' case.

#### Remuneration of General Practitioners at Cottage Hospitals

The Ministry has announced that a general practitioner may provide general medical care as a member of the staff of a hospital in the following capacities: (a) As one of the staff of a general-practitioner ('cottage') hospital, (b) as the part-time medical officer of a convalescent home or other institution. For both these groups it will be necessary to enter into contracts starting on the appointed day.

With regard to the first group, an opportunity will be given to all general practitioners practising in areas served by 'cottage' hospitals to accept appointment to the staff of the hospital. The duties will include attendance as general practitioners on their own patients in the hospital, sharing with the other members of the staff in attendance on the patients of practitioners not on the staff, and taking the appropriate share in any necessary emergency in-patient or out-patient work. In so far as a general practitioner providing general medical services under Part IV of the Act gives hospital care within the scope of these services to a patient on his list or on that of his partner he will already be remunerated for that work through the executive council. But in order to provide proper remuneration for his hospital work for other patients it is contemplated that the management committee shall create a staff fund by making a payment of £25 per annum for each bed (other than private pay-beds) occupied on the average in the hospital, the fund to be shared between the general practitioner staff as they may themselves determine.

With regard to the second group—namely, part-time medical officers of convalescent homes, etc.—the average time given to this work will be assessed and aggregated in terms of half-days per week and a contract will be offered accordingly. The provisional rates of remuneration are to be based on a rate of £100 per annum (non-resident), for each half-day per week up to a maximum of £800 for eight or more half-days, and subject to review when the remuneration of specialists has been determined. The conditions of service will be the same as those laid down as applicable to specialists. An engagement on an honorary basis is not excluded, if the practitioner so desires, provided that there is a clear undertaking to perform defined services.

A number of general practitioners on the staff of 'cottage' hospitals may claim that they are in effect part-time specialists and that their remuneration should be based on the provisional specialist scale. The onus of determining whether or not a practitioner is holding a part-time specialist appointment rests with the regional hospital board concerned on the advice of its appointments committee.

It is understood that appointments committees will re-examine individual cases as soon as possible.

#### Local Obstetric Committees

A question was put to the Ministry of Health about the legal position of doctors acting as members of local obstetric committees. The Ministry has since consulted its legal advisers who consider that members of these committees need not fear that they are likely to be involved in legal proceedings provided that they carry out their duties of considering the obstetric experience of doctors who apply to provide maternity medical services under Part IV of the Act in a proper manner. As an additional insurance it is understood that "the Minister would be prepared to undertake the cost of the defence of any committee against whose members any proceedings are brought and to indemnify their members against any damages and costs ordered in such proceedings provided that the members of the committee have acted reasonably in carrying out their duties as members."

### APPOINTMENT OF SPECIALISTS IN N.H.S

The appointment of specialists by regional hospital boards or boards of governors of teaching hospitals is controlled by the N.H.S. (Appointment of Specialists) Regulations, 1948 (No. 1416). A vacancy must be advertised in two or more journals "circulating throughout England and Wales being commonly used for advertisements of a similar kind relating to the profession concerned." It may also be advertised in other journals or newspapers. The advertisement must state (i) the nature of the appointment, (ii) whether the appointment is for whole time or part-time service, and if part-time the approximate length of time per week which will be required, (iii) the duration of the appointment, (iv) the remuneration, (v) the closing date for the receipt of applications, and (vi) that canvassing of members of the board or advisory appointments committee will lead to disqualification.

An advisory appointments committee must be constituted when a post falls vacant or a new one is created, and is constituted as follows according to whether a non-teaching hospital or a teaching hospital is concerned.

#### Non Teaching Hospitals

The advisory appointments committee shall consist of seven members appointed by the regional hospital board of whom one shall be selected by the board to act as chairman.

Two of the members, of whom at least one shall be a medical practitioner in the case of the appointment of a medical officer or a dental practitioner in the case of the appointment of a dental officer, shall be appointed on the nomination of the hospital management committee concerned or, if two or more hospital management committees are concerned, on the nomination of those committees jointly.

Of the other five members four at least shall be medical practitioners in the case of the appointment of a medical officer, or dental practitioners in the case of the appointment of a dental officer, and at least one shall be appointed after consultation with the university with which the provision of hospital and specialist services in the area of the board is associated.

Of the members who are medical or dental practitioners at least two shall be, or shall have been, engaged in the practice of the special branch of medicine or dentistry concerned and at least one shall be so engaged outside the area of the board.

#### Teaching Hospitals

The advisory appointments committee shall consist of seven members appointed by the board of governors of whom one shall be selected by the board to act as chairman.

Two of the members shall be appointed on the nomination of the university with which the hospital is associated and at least one of such members shall be a medical practitioner in the case of the appointment of a medical officer or a dental practitioner in the case of the appointment of a dental officer.

Of the five members appointed otherwise than on the nomination of the university at least four shall be medical practitioners in the case of the appointment of a medical officer, or dental practitioners in the case of the appointment of a dental officer, and at least one shall be a person appointed after consultation with the regional hospital board of the area in which the teaching hospital is situated or, if the hospital is situated in the area of more than one regional hospital board, after consultation with both or all of such boards.

Of the members who are medical or dental practitioners at least two shall be, or shall have been, engaged in the practice of the special branch of medicine or dentistry concerned and at least one shall be also engaged at some other teaching hospital.

The advisory appointments committee will select from the applicants such persons as it thinks suitable for the appointment and submit their names to the board together with any comments it wishes to make. If the committee thinks that none of the applicants is suitable, it will tell the board so.

### TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization.

*Metropolitan Borough Councils*—Fulham, Hackney, Poplar.

*Non-County Borough Councils*—Dartford, Radcliffe (limited to future appointments), Tottenham, WallSEND.

*Urban District Councils*—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Portslade, Redditch (restricted to new appointments), TylDESLEY.

# British Medical Association

## GROUP PRACTICE AND HEALTH CENTRE DEVELOPMENT SPECIAL MEETING OF COUNCIL

A special meeting of the British Medical Association Council was held on July 14 for the purpose of considering a report by the Health Centre Committee. This is a special committee set up by the Council in April, 1947, to investigate and report on existing forms of group practice, including partnerships and other forms of collaboration between general practitioners, and to relate this and other experience to health centre development. Dr A Talbot Rogers was the chairman of the committee, but as he is not a member of the Council the report was presented by Dr A Beauchamp. Much of the discussion in the Council, over which Dr H Guy Dain presided, concerned phrasing and matters of detail, but certain principles also emerged upon which there was diversity of opinion, and some parts of the report were referred back for further consideration.

### The General practitioner Specialist

The committee reported that the evidence before it had convinced it that partial specialization was a most valuable feature of general practice, that doctors who took part in it widened rather than narrowed the range of their work, and that the general-practitioner specialist was a link between two sections of the profession which, without him, might become dangerously separated.

Dr F Gray urged that the other side of the question should be stated. Leaving out of account those areas where, as they all agreed, some specialization in general practice was a necessity, he felt that such specialization ought not now to be encouraged. It could not, in the nature of things, be first-rate. This was no criticism of the men who had taken up this form of work, but if they were engaged partly in general practice they could not have the same degree of competence and skill in a specialty as the doctor who devoted his whole time to it. There were two conceptions of treatment—namely, the treatment of the disease and the treatment of the patient—and the committee had very wisely emphasized the latter, but specialization was the treatment of selected diseases. This was a withdrawal from the fundamental conception of the family doctor. Furthermore, the energies of the general practitioner in the national service would be increasingly turned in the direction of prevention, the time to exercise prevention was not when patients had some serious illness but when they had a trivial one, but if he specialized the general practitioner would tend to concentrate his attention on the serious cases and to neglect the early (and incidentally the more difficult) ones. If anyone in general practice wanted to specialize there was only one answer to be given him: 'By being a general practitioner you are already doing so.'

Dr J A Pridham spoke in a similar sense. Specialist general practitioners had done good work, but it was questionable whether under the new set-up men should be encouraged to adopt partial specialization. Three general-practitioner specialists known to him had told him that they had not been as good in either field—specialism or general practice—as they would have been had they undertaken one field only. He drew attention to the criticisms of part-time consultants in the article by Mr G Lowe and Dr T N Rudd in the *British Medical Journal* of July 3 (p 24). In his own part of the country the general-practitioner specialist was tending to give up his general practice and to become wholly a specialist. If the general-practitioner specialist was dying out, would the Association be doing right in taking steps to perpetuate him?

Dr P J Gibbons said that, listening to the last two speakers, one would think they had never heard of Sir James Mackenzie, who laid the basis of his great reputation as a specialist while engaged in general practice. If the general practitioner were cut off from the possibilities of specialization it would bring about an unfortunate gulf in the ranks of the profession between

the trained technicians, as he preferred to call them, and the students of general medicine.

Dr R G Gordon considered that, while in the past it had been hard enough for the general practitioner to become a specialist, in the future it would be much harder, because specialists were insisting on five years' study in the specialty, and that was more than the general practitioner could be expected to give. If it was decided that general practitioners should be encouraged to develop specialisms—and personally he thought they should—it might be referred to the Postgraduate Committee just set up by the Council to consider how this should be done.

Mr Dickson Wright said that an immense amount of work would be—indeed, was being—thrown upon specialists, there was widespread demand for specialist attention and the use of specialist equipment, and if the relief afforded by general practitioner specialists was denied the position would be intolerable.

Dr J G Thwaites agreed with Drs Gray and Pridham. They were all agreed that some of the finest specialists had graduated through general practice, but the suggestion in the report that health centres should provide facilities for general practitioners to take up specialties if they so desired should not be supported. Health centres should be a means of clarifying and raising the status of general practitioners as such. They would offer general practitioners a far wider sphere of general-practitioner work, and he hoped that nothing would be done to suggest that if future general practitioners did not take up some specialty they were falling into some sort of rut.

Dr R Kennon said that at the present time students were coming to the universities determined to take up some specialty. The present recruiting ground for specialism was far too narrow. Dr O C Carter, although a part-time specialist himself, supported Dr Gray's contention. It would be a great mistake if in any report which issued from the Council it was suggested that the status of the general practitioner was influenced to any degree by possession of a specialty. It would not be in the interests of general practice to attempt to perpetuate artificial part-time specialties. The Spens Committee had felt that there was ample scope in general practice to satisfy full professional attainment and to reach high academic distinction. Dr J C Arthur, while not expressing any definite opinion on the question of the continuance of the general-practitioner specialist, said that it was important not to discourage the ordinary practitioner from doing as much as possible for himself.

Dr J A Ireland considered it important to keep open the avenues of approach to full specialism by way of general practice. It was in the interests of general practice and of the profession as a whole and of the public that general practitioners should be encouraged to take on any special line. Dr Janet Atken said that there was one branch of specialism—if it could be called specialism, which she doubted—namely preventive medicine—which the general practitioner should never be discouraged from doing. Dr J A L Vaughan Jones gave instances of useful general-practitioner specialism. The National Ophthalmic Treatment Board could not have functioned without the general-practitioner eye specialist. But there was an unfortunate tendency to separate general practice and specialism at the moment of qualification. In the health centre which was the subject under discussion, the team spirit would be developed and within that team many doctors would be able to develop what could be called sub-specialism. Dr J A Brown desired to see in the health centres not so much the development of partial specialization as the development of a special interest in a particular branch of medicine. He hoped to see some doctors in the health centre acquiring a little more knowledge in a particular field than could possibly be acquired

by all their colleagues. This might be done by attaching such doctors, perhaps as clinical assistants, to special hospitals in the area.

The Secretary (Dr Charles Hill) reminded the Council that the burden of the report was not that general practice should be one of the roads to specialism but that the general-practitioner specialist should be encouraged as a means of preventing a certain deterioration in general practice. It positively advocated as essential to the health of general practice the development of the general-practitioner specialist.

The Chairman (Dr Daun) said that Lord Dawson's Consultative Committee in 1920 came to the conclusion that the role of the general practitioner was that of diagnostician, and that he should be given the necessary facilities to keep in training his diagnostic skill. It would be a mistake to suppose that the status of the general practitioner could not be raised to a higher level unless a large number of such practitioners took up some form of specialty. After all, the general practitioner was more interested in the patient than in his complaint. The only substantial way in which general practice could be kept in a state of efficiency was by attention to the diagnostic field.

It was agreed to refer back to the committee this part of the report in order that it might be reconsidered in the light of the discussion.

#### Single-handed Practice

A further discussion developed on the section of the report concerned with single handed practice, in which the committee had expressed the conclusion that the disadvantages of single-handed practice outweighed its advantages. Dr Pridham, while not opposing the principal contention, thought the conclusion was expressed a little too strongly as though the single-handed practitioner were in some way condemned.

Dr S Wand pointed out that, with the advent of the new Service, partnerships had tended to dissolve, so that more and more men were becoming single-handed practitioners. Until the result of this experiment was seen in the big areas it might be well to avoid coming to a conclusion on this matter. Dr G MacFeat pointed out that in many rural areas single handed practice was the only form of practice possible.

Mr A S Gough defended the committee's conclusion and pointed out that the present dissolution of partnerships was brought about purely on financial grounds and had nothing to do with the respective merits of single-handed practice, partnerships and group practice.

The conclusion as stated in the committee's report was modified by making it apply to urban areas only and by making the final sentence read (after mentioning the difficult position of the single-handed practitioner) "but the Council would be opposed to a policy which rendered single handed practice impossible."

On a further section of the report on group practice Dr Wand thought that the committee ought to be asked for more information on what in its view constituted a group and Dr Vaughan Jones pointed out that groups obviously must vary according to the doctors composing them and that no standards could be set up for a particular group to be adopted for the whole country.

#### Planning for the Future

Having surveyed present-day conditions the committee in its report went on to consider what should be the direction of development of general practice under the new National Health Service and how the best features of existing practice might be incorporated in any new system. It pointed out the changes needed and led up to the health centre concept. One of the features of the present system which in the opinion of the committee should be retained or developed was the holding of clinical assistantships in hospitals by general practitioners, it was believed that this helped to retain their standard of work and formed a valuable liaison with the hospital services.

On this point Dr Gordon said it had proved very difficult to make such an arrangement really satisfactory, and he suggested that a small subcommittee should be set up to consider practical ways in which the general practitioner should be incorporated into the staffs of, generally speaking, non-teaching hospitals.

Some discussion took place on whether it was preferable to have general practitioner hospitals or to have the admission of general practitioners into general hospitals.

Dr Thwaites, on a further point concerning the integration of general practice with public health work, said that he would like to see antenatal and maternity and child welfare work not regarded in the future as a separate entity in general practice, but every general practitioner taking his part in the school clinics and welfare centres. The opportunity surely presented itself in experimental health centres to have general practitioners doing this work rather than local authority officers. Dr Gray agreed that there were opportunities here, much to be preferred to the pursuit of the "rosy paths of pseudo-specialism," but there was no proposal to take over the whole thing lock, stock, and barrel and turn the other people out.

It was agreed to enlarge upon what was said in the draft report about uniting the work of family practice with that of the clinics.

#### Health Centres

In considering the services to be provided at health centres discussion in the Council centred round the proposals for the introduction into the health centres of specialists in radiology and of pathological services.

Dr Vaughan Jones urged that there should be some provision for simple radiology and for simple pathology at each centre. No expensive radiological apparatus need be provided. Dr Wand pointed out that such equipment and facilities might be expected to vary with the location of the centre, being more elaborate the further the centre was away from the large hospitals. Dr Gibbons held that there was no sense in cluttering up the health centre with x-ray apparatus when the ease could be better dealt with at the nearest hospital. Other members favoured a modest equipment for specialized services at the centre.

The Council expressed itself as not opposed to such provision, but it was agreed that all the various proposals for visits by specialists to health centres and the use of the specialist appliances available there should be remitted to the Central Consultants and Specialists Committee for its consideration and recommendations.

Discussion also took place on the professional staffing of the centres. One method was set out fully in the report, but it was pointed out that there were other methods and the committee was asked to mention them in similar detail.

On the question of the site of the health centre one member pointed out that the choice of site would largely determine the number of doctors finally working at the centre. The section of the report dealing with the health centre building its general plan and accommodation was approved.

Dr J C Pearce and Dr G MacFeat were of opinion that it was not practicable owing to the scattered nature of the population to have health centres in rural areas and the latter suggested that cottage hospitals, with some provision for consultation would better meet the case.

The committee was of opinion that centres could usefully be adapted to the needs where a population of 10 000 or more was contained within a radius of ten miles but this part of the report was deferred for further consideration. It was felt that in any event rural health centres would be late on the programme.

On the general question it was stated that plans put forward from local authorities were being considered by the Ministry. The design of the pioneer health centre of the LCC at Stoke Newington was, through the kindness of Sir Allen Dray, exhibited before the Council. Therefore it seemed desirable that the proposals of the Association should be known as soon as possible.

It was agreed that the report of the committee except for those portions mainly relating to domestic matters within the profession, which had been deferred for further consideration should be forwarded without delay to local medical committees and the medical members of local authorities. The portions held over related to the question of the general practitioner specialist which was referred back to the committee, the organization of the professional staff also referred back, and the question of attendance of specialists at health centres and the provision of specialist equipment which was referred through the Consultants and Specialists Committee to the groups of specialists particularly concerned.

The discussion on the report occupied nearly five hours.

## FEES FOR MIDWIFERY

The fees payable to medical practitioners when they are called in by midwives in an emergency have been prescribed by the Minister of Health in the Medical Practitioners (Fees) (No 2) Regulations, 1948 (No 1453), which are applicable to England and Wales only. The regulations apply to practitioners on the lists approved by local obstetric committees, though exception is permitted where local authorities have not yet supplied the midwives in their area with the approved list, or where a practitioner on the approved list is not available when the emergency arises. The regulations do not apply in the case where a medical practitioner has arranged to provide the patient with maternity services under the N.H.S. general medical services, or to the practitioner who is attending the patient under some arrangement with a club or other association or is receiving a fee from the patient or on her behalf.

The fees prescribed are normally payable to the practitioner only up to the fourteenth day after his first attendance unless before the fourteenth day he has notified the local authority in writing that his further attendance is necessary. In any case fees are not payable for services rendered after four weeks from the birth. A form is prescribed with which to claim the fees.

The following scale of fees is reproduced from the regulations.

(i) Fee for all attendances of a medical practitioner during the period from the commencement of labour until the child is born, whether or not operative assistance is involved, including subsequent visits to mother and/or child during the first fourteen days inclusive of the day of birth, and including also a post-natal examination at or about the sixth week after the birth, except where owing to circumstances beyond his control the practitioner cannot undertake such examination £4 14s 6d.

(ii) Fee for all or any of the following—namely version in labour, removal of adherent or retained placenta, exploration of the uterus, treatment of post-partum haemorrhage or any operative emergency arising directly from parturition, including subsequent visits during the first fourteen days inclusive of the day of birth, and including also a post-natal examination at or about the sixth week after the birth, except where owing to circumstances beyond his control the practitioner cannot undertake such examination—£4 14s 6d. A fee shall not be payable under this paragraph when a fee under paragraph (i) hereof is payable.

(iii) Fee for a single attendance only, either during the period from the commencement of labour until the child is born (whether or not operative assistance is involved) or for any of the purposes mentioned in paragraph (ii) hereof, £2 12s 6d. A fee shall not be payable under this paragraph when a fee under paragraph (i) or paragraph (ii) hereof is payable.

(iv) Fee for either of the following—namely, (a) suturing the perineum, (b) resuscitation of baby, £3 3s. Provided that where only one attendance is made a fee of £2 12s 6d shall be payable in lieu of the said fee of £3 3s. A fee shall not be payable under this paragraph when a fee under paragraphs (i) to (iii) hereof is payable.

(v) Fee for induction of labour whether or not more than one visit is involved, £2 12s 6d. A fee shall not be payable under this paragraph when a fee under paragraphs (i) to (iv) hereof is payable.

(vi) Fee for attendance at, or in connexion with, an abortion, miscarriage, cases of threatened abortion or ante-partum haemorrhage after the 28th week of pregnancy, including all visits in respect of such attendance during the fourteen days from and including the first visit, £4 4s. Provided that where only one attendance is made a fee of £2 12s 6d shall be paid in lieu of the said fee of £4 4s.

(vii) Fee for attendance of a second medical practitioner to give an anaesthetic, whether on the occurrence of abortion or miscarriage, at parturition or subsequently, £1 15s.

(viii) Fee for visits to mother and/or child not included under paragraphs (i) to (vi) hereof. Day (9 a.m. to 8 p.m.) first visit 12s 6d, subsequent visit 10s 6d, night (8 p.m. to 9 a.m.), £1 1s.

(ix) The usual mileage fee of the district to be paid for all attendances under paragraphs (i) to (viii) hereof. Provided that one mileage fee only shall be paid in respect of one journey, whether such journey shall have been made for visiting one, or more than one, patient.

(x) Fee for attendance on mother or child at the medical practitioner's residence or surgery, 5s.

(xi) The appropriate fee as prescribed above shall be increased by the amount of any reasonable expenses necessarily incurred by the practitioner in supplying any of the drugs or preparations specified

in the following paragraph where such a drug or preparation is essential for the proper treatment of the mother or her child.

*List of Drugs and Preparations*—Carbon dioxide, ergometrine, lobeline, liver extract and injections of liver, methylamphetamine, oxygen, penicillin preparations, pethidine, sex hormones, sulphoamide preparations, vasopressin, vitamin B<sub>1</sub> complex, vitamin K.

## HEARD AT HEADQUARTERS

### "Greta Garbos of Medicine"

The Minister of Health has been endowed with considerable oratorical gifts, but every now and then his fluency gets the better of him and some bitter remark emerges to discomfort his friends and perhaps ultimately himself. In the middle of some quite graceful passage he will interject an observation causing quite unnecessary offence. A week or two ago, addressing the Maternity and Child Welfare Conference in London, he contrasted the prosaic work of the public health medical officer with the more dramatic work of the surgeon. So far so good, but he went on to deliver himself of this sentence:

Surgeons call our attention to the spectacular consequences of their skill, the Greta Garbos of medicine can get the lime light because what they do is spectacular, but in this field of public health "and so on. The tribute to the public health service is of course deserved, but need it be associated with apparent derogation of surgeons—if it is derogation (some may not think so) to liken them to a glamorous film star? The other day at the National Institute for the Deaf, Mr Bevan went out of his way to suggest that commercial jealousy on the part of hearing-aid manufacturers might be prejudicing the Government hearing aid. No evidence for this was brought forward. One would have thought, on the contrary, that the long and patient research work done under commercial auspices has assisted the development of the Government aid.

### Return of the Snuffbox

Is the doctor's snuffbox coming back? At the Oxford Ophthalmological Congress last week two prominent ophthalmic surgeons were observed to be taking elegant pinches. One of them sat in front of the lecture theatre opposite a notice which said "No Smoking" and seemed to glory in this alternative indulgence, which has no reproach. The same thing was noted among some of the doctors assembled at Cambridge. The snuffbox along with the gold-headed cane was part of the regalia of the old-time physician, and we believe that a silver snuffbox is one of the treasures of the Hunterian Society, displayed on every full-dress occasion, together with the loving cup. We recall hearing Sir Buckston Browne declare that the use of snuff had proved a perfect prophylactic against colds, but, aware of the dangers of over-indulgence, he took the precaution of placing his snuff jar in the attic of his tall Harley Street house, so that whenever the desire seized him he had to pay for it by a climb up four flights of stairs. Meanwhile the path of the smoker becomes increasingly difficult. A requisition—from lady members be it noted—that smoking should be permitted in the new B.M.A. library at Tavistock Square has been turned down by a hardhearted Council.

## THE SCHOOL MEDICAL OFFICER

Many public- and preparatory-school authorities have recently advised parents that boarders should be registered with the school doctor if he has accepted service under the National Health Service, and that during holidays such boarders will be entitled to attendance as "temporary residents" from the home doctor or from any other doctor taking part in the scheme. While there may well be difficulties in permitting doctors other than the school doctor to use the school sanatorium, the policy adopted by certain schools is in direct conflict with the principle of "free choice" of doctor. Indeed, many will argue that the home doctor should be the regular medical attendant, since he is in possession of the child's clinical record and has an intimate knowledge of the child's home and general environment. In any case the last word about the choice of doctor should remain with the parents. Representations are being made to the Associations of Headmasters and Headmistresses with a view to ensuring the maintenance of this vital principle.

## Correspondence

### Thanks to Clerical Staff

SIR,—We propose a very hearty vote of thanks to the Association's clerical staff for their work both in preparing for, and during, the A R M at Cambridge. As the Secretary said on the first day of the conference, "Nothing is impossible for the staff to do." How many of us who spent our evenings in pleasure-hunting thought of the clerks? They finished work at these times: Friday, 9 p.m., Saturday, 6 p.m., Monday, 12 midnight, Tuesday, 10 p.m. They started earlier than we did each morning, and besides their official work they always seemed to be able to do odd jobs for individual representatives, and do them with a smile. We regret that we had no opportunity of putting this to the meeting in Cambridge.—We are etc

### The First Three Months

SIR,—Now that our Minister is so anxious to support and encourage us, would you ask him to take a small step to see that all these non-intransigent doctors who have signed on in good time shall not lose three months' pay in respect of each member of the public who has failed to obtain an E.C.1 in spite of repeated visits to more than one post office? I would suggest that all patients registered before Sept. 30 be credited for payment as if on the doctor's list on July 5.—I am, etc.,

Crowthorne Berks

H D FORBES FRASER

### Domiciliary Maternity Service

SIR,—The farce of paying the G.P. who is judged safe to practise midwifery 7 guineas, and the one judged unsafe 5 guineas, is not, alas, the worst of it. Under the N.H.S. a woman not only does not get a doctor at her (normal) confinement, but she is actually debarred from making an arrangement which will guarantee her one. The G.P. is paid 7 guineas, and for this he is expected (1) to make two antenatal examinations, (2) to attend the confinement if he deems this necessary or if the midwife sends for help, (3) to supervise the puerperium for a fortnight, and (4) to make a post-natal examination at six weeks. This service is adequate only if there is a competent midwife doing the regular antenatal examinations and attending the confinement, and this in fact means the district nurse. For patients who are delivered in nursing-homes or who have their own monthly nurse there is no provision whatsoever, and the patients will be driven outside the Service as the only method open to them of getting the attention they want. Moreover, many women who are attended in their homes by the district nurse will want their own doctor to be present at the confinement, and again they must be told that they cannot have this unless they resign from the Service.

The effect on the doctor will be no less bad, for he will largely cease to see normal midwifery and will only see the abnormal. He will not develop that good judgment of when to interfere and when not to interfere which comes only from long, patient, and repeated vigil with the normal confinement.

The solution is perfectly clear. It is the duty of the State to supply adequate basic treatment, and this the district nurse with the supervising G.P. can give. But the patient should be left free to pay her doctor for attending her at her confinement if she wishes.—I am, etc.,

Newbury Berks

T G SCOTT

### Generous Health Authorities

SIR,—A few weeks ago you commented in "Heard at Headquarters" (June 5, p. 156) on the action of the Middlesex County Council in sending a patient with tuberculosis to Switzerland for treatment. I should like to bring to your notice the action of my Council in similar cases.

At present there are at least four patients from East Sussex receiving treatment for tuberculosis in Switzerland. Two of these

made private arrangements and asked us to assist them financially. This we are doing to the extent of what their treatment would cost us had they been receiving treatment in this country. One went to Switzerland on our own recommendation and is satisfied with, and grateful for, similar financial help. The remaining patient, a young boy of 7 or 8, was sent by us to Switzerland for treatment which was not available for him here, and we pay the full cost of his treatment and travelling expenses. Moreover, the County Council makes a grant of £10 every three months, irrespective of care committee or other help, towards the expenses of a relative to visit this boy—the only English lad in the sanatorium.

I should be surprised if other authorities could not give similar examples of their liberal interpretation of their responsibilities while they have been responsible for the treatment of tuberculosis.—I am, etc.,

A H FERGUSON GOW,  
Senior Chest Physician,  
East Sussex County Council

Lewes Sussex

### Medical Trade Union

SIR,—The decision of the Annual Representative Meeting to refer consideration of forming a medical trade union to Council is wise, as time and thought must be given generously to the problem. Before a final step is taken the widest possible discussion and publicity should be encouraged, and even the useful but recently much maligned procedure of a plebiscite might again be undertaken. It is possible that there could be a tightening up of our technique for collective bargaining to gain improved conditions and terms of service. The Whitley Council may prove the correct answer.

It is not so certain that a drastic alteration in our policy-making machinery is either necessary or desirable. There might be danger to our freedom of action both from without and within our organization. Affiliation to the T.U.C. might mean that we should be subjected to pressure by that body to take or condone actions totally at variance with our dignity and interests as a profession. Trade union status might also place in the hands of our own executive, or of an energetic minority in our Council, such overriding powers that they might be tempted to pursue any policy without first making certain, by referendum or otherwise, that it commended itself to a sufficient majority of our members.—I am etc.,

### Blaming Doctors

SIR,—In *The Times* of July 3 the Parliamentary report gives extracts from a debate on the forthcoming National Health Service. In this report there are certain Ministerial implications which cannot be allowed to pass without comment. I refer to the placing of blame at the feet of the medical profession for their tardiness in joining the new Service. At the same time, in to-day's issue of the *Sunday Times* there is the following statement: "It seems clear that the Ministry is formulating a practice of passing to the doctors the blame for any of the deficiencies in the scheme." And in another leading daily paper we read that the last-minute rush of doctors to sign on is evidence of the medical profession's degree of confidence in those responsible for implementing the National Health Act.

This is the time for dealing with facts and not with phantasies, and briefly, Sir, the facts of the situation are as follows:

1 The B.M.A. has had to fight hard for some twelve months in order to secure amendments to the *National Health Service Act* whereby the profession may be enabled to give the public the best, most reasonable, and most adequate service in their power. At the same time the B.M.A. has been fighting to preserve the greatest possible measure of professional liberty for the individual doctor so that he may be able to do the best for his patients.

2 It was not until the end of May—six weeks before the new service was due to begin—that sufficient safeguards had been promised to the profession for the B.M.A. to encourage its members to undertake service under the Act.

3 Hence in part the last-minute rush to sign on. But an equally important factor has been the use of unilateral economic pressure (for which there is a short and ugly word) "Unless you join by July 5 you get no compensation for your practice." These are the reasons for the indecent haste.

4 As for the apportioning of blame, let it be clearly understood that the medical profession will do its utmost to give the best possible service to the people of this sorely tried country, and the majority of us are prepared to go on working 70 to 80 hours a week, as we have been doing, in order to heal the sick. I trust and pray that we shall not be pilloried for our efforts, despite the fact that many situations are bound to arise which will warrant reference to two famous aphorisms "You cannot make bricks without straw", "Don't shoot the man at the piano, he is doing his best"—I am, etc.,

Manchester

DAVID R. GOODFELLOW

## POINTS FROM LETTERS

### Mr Bevan's Two Messages

Dr N B COOKE (St Helens, Lanes) writes. In your issue of July 3 you publish an address purported to come from the Minister of Health exhorting the members of the medical profession to join with him in the successful working of the National Health Service. This address was given priority of place in your publication. While many of us were reading this eulogy over the week-end Mr Bevan was telling 7,000 people in Manchester that he hated the Tory Party and that he considered its members worse than vermin. Was there ever such a piece of two facedness? All the world, particularly the professional part of it, is watching the colossal experiment that commenced on July 5 and my object in taking up your valuable space is to ask those members of our profession who have cared to make Mr Bevan their champion what they think of this latest effort on the part of the Minister. I should imagine that even the staunchest member of the Socialist medical fraternity must have been rather shocked on opening his daily paper on Monday morning—that is of course, if the Socialist press published this part of his speech. I should also imagine that those doctors who reversed their decision to fight at the second plebiscite must have been badly shaken. Our leaders have advised us to co operate with the Act and to put our faith in the Minister and his assurances. Let us hope their advice will not be misplaced. Nevertheless, such a beginning does not augur very well for the future.

### Medical Records

Dr C COLEY GRAYSON (Birmingham) writes. Now that the National Health Service has started and medical records are being issued to us for the whole population, may I repeat a suggestion which I made some years ago about record keeping—namely, that the back of the record envelope be left blank of detail and reserved only for entering *salient points* in medical history? These points will thus be able to be seen at a glance instead of searching through a mass of detail on continuation cards.

### Free Bottles

Dr A P KALRA (London, SW 9) writes. On the back of the prescription sheets to be used for the purpose of the new health service it is stated that bottles for medicines will be supplied free. No mention is made of a deposit charge. That such should exist is obvious, to avoid wastage and a possible shortage of bottles at some future date.

## LUNACY AND MENTAL TREATMENT

Rules have been made amending the Lunacy Act 1890. Form 10 is replaced by the following form.

*Certificate as to patient in hospital designated for the purposes of Section 20 of the Lunacy Act 1890*

I hereby certify that I have carefully examined into the state of health and mental condition of \_\_\_\_\_ and that he is in my opinion of unsound mind and that it is expedient for his welfare that he should be detained in this hospital for a further period not exceeding fourteen days from the date of this certificate.

The grounds for my opinion that the said \_\_\_\_\_ is of unsound mind are as follows —

(Signed)

Dated

Medical Officer,

Hospital

In addition, the duly authorized officer for the purpose of the Lunacy Act 1890 must describe shortly on Form 12 any property owned by the patient if it exceeds £100 in value.

## H.M. Forces Appointments

### ROYAL NAVY

Surgeon Commander J M Sloane to be Surgeon Captain

### ROYAL NAVAL VOLUNTEER RESERVE

Surgeon Commander J B Oldham V R D, to be Surgeon Captain  
Surgeon Lieutenant Commanders S B Levy, V R D, and D R Hughes, V R D, to be Surgeon Commanders  
Temporary Acting Surgeon Lieutenants P K O'Brien, J S Finnie, W A Copeland, M Strode, R M Foster, C McLeod, W F M Hudson, H G Dixon, J Candy, J R Brotherton, and G F Barnes to be Temporary Surgeon Lieutenants

### ARMY

Colonel G S McConkey, OBE late R A M C, has retired on retired pay, and has been granted the honorary rank of Brigadier.

### ROYAL ARMY MEDICAL CORPS

Lieutenant-Colonel W H A D Sutton, OBE, has retired on retired pay, and has been granted the honorary rank of Colonel.  
Major H V Stanley, MBE, MC, retired and re-employed on ceasing to be re-employed has been restored to the rank of Lieutenant-Colonel.  
Majors (War Substantive Lieutenant-Colonels) L G Irvine, D M Ahern DSO, to be Lieutenant Colonels.  
Major D J H Jones has retired on retired pay.  
Captains D B Watson and E J Bowmer to be Majors.  
Captain (War Substantive Major) G S Caithness to be Major.  
Short Service Commissions—Major W N S Donaldson T A to be Captain. Lieutenants C W Bowen, J A H B, R D Calcott, P F Daly, and P J Roden to be Captains.  
E R Reid to be Lieutenant.

### WOMEN'S FORCES

#### EMPLOYED WITH THE R A M C

Lieutenant B Cregan to be Captain

## Association Notices

### FILM LIBRARY

The B M A is endeavouring to establish a comprehensive film library for the convenience of Branches and Divisions and other interested bodies. It is anxious to obtain as many suitable films as possible. Medical practitioners who have produced medical films and are willing for copies to be made and included in the library are invited to communicate with the Secretary of the Association, giving particulars of their films. Copyright would remain in the hands of owners, full acknowledgment would be made and the cost of copying borne by the Association.

### B M A LECTURES

Every Branch and Division may have one B M A Lecture a year. The lecturer, who is chosen by the Branch or Division is an authority on his particular subject. He is invited from the Central Office and receives an honorarium and his expenses. Branch and Divisional secretaries making up their programmes for the forthcoming year are invited to send requests to Headquarters for B M A lectures. The application should be on a special form obtainable from Headquarters denoting the name of the lecturer, the subject, and choice of dates.

### Branch and Division Meetings to be Held

MARYLEBONE DIVISION—At Medical Society of London, 11, Chandos Street W, Monday, July 26, 8.30 p.m. Agenda: To report on (1) Special Representative Meeting held on May 28, (2) Annual Representative Meeting held at Cambridge.

to overcome what was still the chief impediment to progress—namely, the intimate association of medical science with astrology. Upon this outlook Gilbert's influence was salutary because of his insistence upon observation, experiment, and deduction and his scorn for reliance upon nothing more than ancient or astrological authority.

### The Seventeenth and Eighteenth Centuries

HARVEY (1578-1657) great work on the application of physical principles to physiology may be regarded as a natural extension of Gilbert's experimental methods. In Cambridge the period of the early seventeenth century was marked by the appointment of Francis Glisson (1597-1677) to the regius chair. Glisson's name is familiar to every medical student who reaches the stage of the second M.B. He was a master in the art of exact clinical observation and in the accurate study of morbid anatomy. He began a phase of medicine which was to last for more than two centuries—a period of individual medicine when the physician with no more equipment than his five senses, his experience, his instinct, and his knowledge, would deduce the diagnosis from acute and penetrating observation and would prescribe such remedies as were known or were believed to be effective. Glisson's name will be familiar to all who are interested in medical history because of his original observations on rickets, or *morbus anglicorum*, and for his classical work on the anatomy of the liver.

One can pass naturally from Glisson to the eighteenth period of the gold-headed cane, which signified wealth and in the social status of the physician gave the medical trend of the century was represented by the two somewhat colourless regius professors who occupied the chair during almost the whole of the century, but by William Heberden (1710-1801) a realist of a rational system of materia medica. He would not pander to mere tradition and of the views of even distinguished men. For his opinion upon Sydenham's belief that jaundice hysteria was, "No reasonable deference to this observer could make anyone very much doubt that he was mistaken."

Heberden flourished during the time of the first professorships in anatomy and chemistry at Cambridge. He must have seen and scoffed at the medical cabinet of William the chemistry professor, which may still be seen at Queens College and which contains such late seventeenth century remedies as dragon's blood, balm of Gilead, viper, scorpion, and the claws of crabs.

### The Nineteenth Century

The end of the eighteenth century was marked by a crucial epoch-making adventure in experimental medicine which was a prophetic prelude to the triumphs of the nineteenth century. The two centuries, and which even to-day stands out as an unprecedented achievement in preventive medicine. It was the work of Edward Jenner's successful cross-immunization experiments with cowpox, the application of which has not been surpassed from this country a disease which at one time had an appalling mortality and caused disfigurement and disability to thousands. This experiment by a general practitioner, which we now accept as a rational piece of science, is far in advance of the times and was inspired by clinical observation, by one who knew nothing of immunological and bacteriological knowledge as we possess to-day. When one comes to the nineteenth century Jenner's vision begins to be seen in the work of the great men then onward to the present day, a greater and greater knowledge of the whole search for the truth to which

ment of the scientific aspect of medicine until at a stage, albeit not a final one, when no one man to be highly skilled in more than one small corner of the fabric of medicine.

From the middle of the nineteenth century onward causes of disease were brilliantly revealed with the work of Pasteur, Koch, and others in the bacterial field; Ross, Bruce, and Leishman in the realm of parasitology; Mellanby, Gowland Hopkins, and others with vitamins; Harington, Banting, Best, Dodds, and others with secretions; of Ehrlich, Domagk, Fleming, Florey, and others with specific chemotherapy. In parallel there grew up an immense accumulation of knowledge of habits and mode of life of parasites and of the complex science of immunology which has elucidated some of the mechanisms by which the body eliminates an infection. Some of the methods by which the protective powers of the body can be increased, and some of the means by which organisms and parasites exert their pathogenic action.

The co-ordination and application of all this knowledge greatly changed the face of medicine between the closing years of the nineteenth century and the opening and subsequent years of the twentieth. Not much more than fifty years ago, as I have shown, certain drugs and treatments were being used with much art, with some skill, and with certain success, but only for the alleviation of the symptoms of a disease. There was little or no knowledge of the action of the drugs, if any, or of the primary cause. With the discovery of the causes of disease the way became open for rational therapy based upon a knowledge of the cause, and this has yielded us the handsomely responsive five per cent, and this we draw to-day.

Yet there were some in the eighteenth century who then resumed their period when nursing and difficulty of cure, who were by and laments, as the patient then of medical knowledge necessary to establish it as in the case of his *Commentaries*. Remedies have just been taining the powers of "specific" may be in information Hippocrates, the legend, quicksilver for venereal disease, cal truths. He said opium for some spasms, pressure promises. However, more outspoken in his age, he claimed for Peru more medicine even as late as the ally may disorders, supply of medicine even as late as the ally may Oliver Wendell when he said "If with two exceptions, the whole materia medica of the nineteenth century swept to the bottom of the sea it would be a place in both the fish market and the bottom of the sea." During the 89 years of his life he witnessed changes in medicine which he never likely to be rivalled. This might be years ago we were not aware of how much the speed of advance has been since Allbutt's death in 1925. Allbutt was a pioneer before the introduction of anaesthesia, he saw the development of bacteriology and immunology, of antiseptic aseptic surgery, of Ehrlich's pioneer work on chemotherapy, including the perfection of salvarsan and he saw the creation of the nursing profession, astonishing progress in public health and preventive medicine, the discovery of X-rays and radium and of vitamins, as well as their application to medical practice, and the development of cardiology, biochemistry, and many spheres. At the end of the century the face of medicine was so different that the whole search for the truth to which

quite small apparatus the transmutation of elements is ele-  
mentary, and radioactive isotopes of almost any ele-  
ment can be produced. These isotopes, used as so-called  
"tracers," have revolutionized many of the body processes, body  
chemistry, and many years

6 JULY 3, 1948

CHANGING FACE

Achievements of the Past Decade

There is no more than gla-  
rious achievements of the past ten years. Al-  
though the work which Allbutt saw in its  
early days First came to mind the advanc-  
ment of the science fathered by Ehrlich in the  
century, which has enabled us to cor-  
rect and parasitic diseases. It is little  
known since the first sulphonamide gave  
us a measure over streptococcal, meningococ-  
cal and bacillary infections. Exploitation of  
the group led to potent specific measur-  
ment of pneumonia, "the captain of the  
march" bacillary dysentery—a disease of  
importance when armies have to fight in  
tropical climates.

During the past decade Fleming's (1)  
penicillin was perfected by co-ordinated  
work, making available for everyday use an-  
tibiotic close to Ehrlich's dream of a ma-  
jor agent, one of the most power-  
ful commonly mortal staphylococcal in-  
fections greatly reduced the mortality  
of wound sepsis during war, and a ma-  
jor consideration frequency in bac-  
terial diseases which hitherto has defied  
quite apart from cure. Following  
organized research into the antibacter-  
ial by other moulds and micro-organisms  
production of penicillin which is  
in the treatment of the acute forms of  
infectious diseases in chem-  
ical laboratories.

human life rather than those which resemble or are in-  
to it." The chronic diseases and the degenerative  
processes which cripple and disable in the latter phases of  
and the uncontrollable activity of the malignant cell,  
as yet not comprehended, much less controlled

The problems of medicine are indeed almost unfath-  
able, and these very facts are part of the fascination  
medical life. In effect, we know relatively little, and  
sometimes wonders whether the public would put such  
trust in us if they properly realized our limitations. We  
have not yet begun to fathom the secret of vitality—that  
property which gives even to the smallest and simplest cell  
the power to accomplish, in a brief moment, chemical  
reactions which years of labour in a laboratory cannot re-  
produce. Think of the bacteria, in which, as Mudd (1948)  
has said, "the structure so far revealed, even with the  
electron microscope, is so much simpler than the remark-  
able synthetic capacities of micro-organisms would seem  
to require. The bacterial cell, when furnished with nothing  
more than water, salts, glucose, and simple sources of  
carbon, and nitrogen, can synthesize proteins, complex  
carbohydrates, lipids, ribose, nucleic acid, growth accesso-  
ries and enzymes, all organized in a characteristic and  
reproducible protoplasmic system. The bacterial cell can  
reproduce itself and divide within half an hour at body  
temperature. These feats of chemical synthesis and  
organization which cannot be duplicated by the finest  
chemical laboratories, are accomplished within a cell a  
few microns in length and less than a micron in diameter.  
The plain facts would be fantastic were they not so  
familiar."

With this sobering thought in mind, and with the  
realization that the nationalization of our profession must  
inevitably increase restrictions on individualism which  
adversely affect the science have themselves initiated, let us hope  
will always be elbow-room for a man to work  
his ideas, to be outspoken in criticism and in  
to be free from unnecessary restrictions,  
and regimentation

But by looking back into history I hope I have made it  
abundantly clear that individualism has done so much in  
the past that were it to be extinguished either by the State,  
by easy living, by regulated hours or indeed regulations of  
any kind, or by too much insistence upon plans and plan-  
ning, then the future changes in the face of medicine will  
never reach the same heights of achievement as in the  
past.

But by looking back into history I hope I have made it  
abundantly clear that individualism has done so much in  
the past that were it to be extinguished either by the State,  
by easy living, by regulated hours or indeed regulations of  
any kind, or by too much insistence upon plans and plan-  
ning, then the future changes in the face of medicine will  
never reach the same heights of achievement as in the  
past.

## CONTINUED HYPERTENSION\* PROGNOSIS FOR SURGICALLY TREATED PATIENTS

BY

REGINALD H. SMITHWICK, M.D.

(Boston, Massachusetts)

From October, 1938, to April, 1943, 263 unselected patients having so-called essential or malignant hypertension of the continuous variety were treated surgically. A thorough exploration of the splanchnic bed was performed in two stages spaced eight to ten days apart, utilizing the lumbo-sal (thoraco-lumbar) technique (Smithwick, 1940). The purpose of this communication is to discuss the present status of these patients, all of whom were operated upon at least five and at most nine and a half years ago. This report deals with 256 patients, or 97.3% of the total material, the other seven cases could not be traced. The investigation was prompted by the high mortality rate for patients in the later stages of hypertensive cardiovascular disease.

### Method of Study

The cardiovascular status of these patients was evaluated before and after operation as carefully as possible, with particular reference to the cerebral, retinal, cardiac, and renal areas. The eyegrounds were examined and described by an ophthalmologist and classified into grades or groups conforming as closely as possible with those of Keith, Wagener and Barker (1939). The heart was studied by means of the electrocardiogram and x-ray films, and evaluated clinically by a cardiologist. Information regarding the kidney was obtained by means of urinalysis, concentration tests, intravenous phenolsulphonphthalein excretion, with particular reference to the output in the first 15 minutes and the total output in two hours, and non-protein nitrogen determination. Intravenous pyelograms were obtained as a routine. Further information was obtained by gross inspection and, in some patients, by biopsies of the kidneys at the time of operation.

A special attempt has been made to acquire certain blood-pressure data on all patients in a standard fashion. These were obtained by performing a so-called postural and cold test, a modification of the Hines-Brown (Hines and Brown, 1933) cold test, after a period of two days of physical inactivity and bed rest. Patients whose diastolic blood pressure fell to below 90 mm during this preliminary rest period were not included in this series, but were classified as having intermittent hypertension, which is regarded as an earlier stage of the disorder. The postural and cold test is performed in a quiet room after a rest period of 15 or 30 minutes on a comfortable bed. Readings of pulse and blood pressure are taken every minute for five minutes with the patient first lying, then sitting, then standing. When the average of the five readings in each position is calculated the figure for the resting horizontal

position is almost invariably the lowest, and is used to divide patients into various groups according to the average resting diastolic level. This same figure is also used to divide patients into three types dependent upon the width of the pulse pressure in relation to the diastolic level. In Type I are placed those cases in which the pulse pressure is less than one-half of the diastolic pressure. Type II contains those cases in which the pulse pressure is equal to or is up to 19 mm more than one-half the diastolic pressure. Type III includes those cases in which the pulse pressure is 20 mm or more greater than one-half the diastolic pressure. After the postural test the patient assumes the horizontal position, and readings of pulse and blood pressure are continued at minute intervals for five minutes. One hand is then placed in ice-water for 60 seconds and readings of pulse and blood pressure are taken after 30 and 60 seconds of immersion. Readings are then resumed at intervals of a minute for five minutes. The patient then stands and the cold test is repeated exactly as in the horizontal position.

The purpose of these special tests is to obtain information concerning variations in blood pressure in response to the stimuli of posture and cold, and also to obtain information regarding variations in the width of the pulse pressure. Such variations may be very striking, and eventually may be used as a basis for further subdividing hypertensive patients into more similar categories. Finally a sedative test is performed. After a light supper the patient is given 3 gr (0.2 g) of sodium amylal by mouth at 7, 8, and 9 p.m. Hourly readings of pulse and blood pressure are recorded from 7 p.m. to 7 a.m. The lowest recorded level of systolic and diastolic pressure is taken as indicating the response.

### Data Pertaining to Pre-operative Status and Corresponding Mortality

Male patients comprised 39.4% and female patients 60.6% of the series. The total mortality during the 5-9-years period of observation was 31.2%. The mortality among males was 34.3% and for females 29.1%. The difference in the mortality rates in the two sexes was slight (Table I). The mortality per operation was 2.2% and per case 4.3%. The causes of death are summarized in Table II.

TABLE I—Mortality 5-9 Years After Operation

	No. of Cases	Living	Dead
Males	102 (39.4%)	67 (65.7%)	35 (34.3%)
Females	154 (60.6%)	109 (70.9%)	45 (29.1%)
Total	256 (100.0%)	176 (68.8%)	80 (31.2%)

\*Read in opening a discussion in the Section of Surgery at the Annual Meeting of the British Medical Association, Cambridge, 1948.

TABLE II—*Causes of Death*

	No of Cases		No of Cases
Cerebral	38 (47.5%)	Unrelated	8 (10.0%)
Cardiac	18 (22.5%)	Unknown	3 (3.8%)
Renal	13 (16.2%)		
		Total	80 (100.0%)

TABLE III—*Age Distribution*

Age	No of Cases	Mortality 5-9 Years after Operation
-10	1 (0.4%)	100.0%
10-19	4 (1.6%)	75.0%
20-29	27 (10.2%)	18.5%
30-39	90 (35.1%)	33.3%
40-49	112 (43.8%)	28.6%
50-59	21 (8.5%)	42.8%
60+	1 (0.4%)	0.0%
Total	256 (100.0%)	31.2%

The age distribution is indicated in Table III. It is apparent that the great majority of the patients were below 50 years of age. The mortality was highest in those below 20 and above 50. The bulk of the patients were between 20 and 49 years of age, and the average mortality for these age groups was essentially the same as for the series as a whole.

If patients were arranged according to pre-operative average resting diastolic levels it was apparent (Table IV)

TABLE IV—*Distribution at Pre operative Resting Diastolic Levels*

Diastolic Level	No of Cases	Mortality 5-9 Years after Operation
90-99	21 (8.2%)	4.8%
100-109	33 (12.9%)	9.1%
110-119	51 (19.9%)	27.5%
120-129	61 (23.8%)	27.8%
130-139	39 (15.3%)	30.7%
140+	51 (19.9%)	64.8%
Total	256 (100.0%)	31.2%

that the mortality increased with the height of the blood pressure. For cases with levels below 110 mm it was lowest, for cases with levels between 110 and 139 mm it was much higher but relatively constant, and for those with levels of 140 mm or more it was very high. At all levels the mortality rate was slightly greater for males than for females.

When the patients were arranged into groups according to the changes noted in the eyegrounds as suggested by Keith, Wagener, and Barker it was apparent in this series, as in theirs, that the prognosis became poorer as the grade of eyeground abnormality increased (Table V).

TABLE V—*Pre operative Eyeground Distribution*

Grade of Eyegrounds	No of Cases	Mortality 5-9 Years after Operation
N	12 (4.7%)	16.7%
1	67 (26.1%)	13.8%
2	68 (26.6%)	26.3%
3	70 (27.3%)	45.7%
4	39 (15.3%)	48.8%
Total	256 (100.0%)	31.2%

TABLE VI—*Pre operative Cardiovascular Status\**

	No of Cases	Mortality 5-9 Years after Operation
Congestive failure and poor renal function	11 (4.3%)	100.0%
Congestive failure	23 (9.0%)	56.6%
Poor renal function	30 (11.7%)	53.3%
Cerebral accidents	39 (15.2%)	38.5%
Grade 3 eyegrounds	34 (13.3%)	29.4%
Grade 4 eyegrounds	15 (5.9%)	24.7%
Abnormal ECG enlarged heart or both	59 (23.0%)	13.5%
Grade 2 eyegrounds	19 (7.4%)	10.5%
Grade 1 eyegrounds	24 (9.4%)	4.2%
Symptoms only	2 (0.8%)	0.0%
Total	256 (100.0%)	31.2%

\* In these ten subdivisions the status of the cardiovascular system as indicated by each heading was regarded as the most important abnormality of the cases in each category.

It was also informative to arrange cases according to other criteria of cardiovascular disease. The prognosis for surgically treated patients appeared to depend upon the original cardiovascular status (Table VI). Of those with poor renal function and congestive heart failure, for instance, no patient survived for five years after operation. The mortality in this group was 100%. At the other extreme were cases with minimal, grade 1 eyeground changes only. The mortality in this group was 4.2% during a similar period of observation. It was noteworthy, however, that in the whole series, all of whom had continuously elevated blood pressure, only two patients (0.8%) had no evidence of cardiovascular damage at the original examination.

### Effect of Operation Upon the Cardiovascular System

The effect of operation upon the cardiovascular system may be judged by comparing the status of the eyegrounds, the electrocardiograms, and the renal function of living patients before and from five to nine years after operation. Of the 176 living patients 129 have been restudied five to nine years after operation, and such data as were available regarding the various vascular areas of these patients at the time of writing are summarized in Tables VII-IX. The

TABLE VII—*Eyegrounds Living Patients*

Pre operative Status		Status 5-9 Years after Operation						
Original Grade	No of Cases	Final Grade					Improved	No Change
		N	1	2	3	4		
N	6	0	4	2	0	0	0.0%	0.0%
1	40	5	21	14	0	0	12.5%	52.5%
2	32	5	3	20	4	0	25.0%	62.5%
3	27	2	2	17	6	0	77.8%	22.2%
4	15	2	7	5	1	0	100.0%	0.0%
Total	120	14	37	58	11	0	40.7%	39.2%

TABLE VIII—*Electrocardiograms Living Patients*

Pre-operative Status		Status 5-9 Years after Operation		
Status	No of Cases	Improved	No Change	Worse
Normal	55	14.5%	80.0%	5.5%
Abnormal	70	64.3%	24.3%	11.4%
Total	125	42.3%	48.8%	8.9%

TABLE IX—*Renal Function Living Patients*

Pre operative Status		Status 5-9 Years after Operation		
Status	No of Cases	Improved	No Change	Worse
Normal	72	0.0%	93.2%	6.8%
Slightly impaired	26	77.0%	7.6%	15.4%
Moderately impaired	12	75.0%	8.3%	16.7%
Markedly impaired	4	100.0%	0.0%	0.0%
Total	114	28.9%	61.3%	9.8%

Renal function was judged by the intravenous pheno'sulphophthalein test. Normal excretion of 25% or more of dye in 15 minutes and 60% or more in 2 hours. Slight impairment: excretion of 20 to 24% of dye in 15 minutes or 50 to 59% in 2 hours. Moderate impairment: excretion of 15 to 19% of dye in 15 minutes or 40 to 49% in 2 hours. Marked impairment: excretion of less than 15% in 15 minutes or less than 40% in 2 hours.

remaining 47 living patients have been checked during the 1-5-years period, but have not as yet been restudied during the 5-9-years interval.

With regard to the cerebral area, 39 patients had vascular accidents or encephalopathy before operation. Of these, 24 are living. Five have had subsequent cerebral accidents of a minor and non-fatal nature. Six of the 15 dead patients in this group of 39 had fatal cerebral accidents following operation. Of the living patients who did not have cerebral involvement before operation, three of 105 cases have had cerebral accidents during the 5-9-years period following operation. Of the 77 patients who have

TABLE X—Cardiovascular Status Living Patients

Pre-operative Status		Status 5-9 Years after Operation		
Vascular Area	No of Cases Examined	Improved	No Change	Worse
Retinal	120	40 7%	39 2%	20 1%
Cardiac (E C G)	125	42 3%	48 8%	8 9%
Renal	114	28 9%	61 3%	9 8%
All (including cerebral)	100	51 0%	12 0%	37 0%

died since operation in which the cause is known with reasonable certainty, death was due to cerebral accidents in 38. If one takes all vascular areas into consideration it will be noted that although certain patients show improvement in one they may at the same time show progress of vascular damage in another area. In other cases there was progress in one or more vascular areas. In still others there was no progress in any area, while some cases showed improvement in one or more areas with no evidence of progress in any area. A composite picture of the patients considered as a whole is given in Table X, in which the changes in the retinal, cardiac, and renal areas already described are summarized, together with an evaluation of all areas in the first 100 cases to be checked in detail five to nine years after operation.

#### Effect of Lumbo-dorsal Splanchnicectomy Upon Blood Pressure

In previous reviews (Smithwick, 1944, 1947, 1948) it has been noted that the blood-pressure levels have been lowered markedly to slightly in the majority of unselected patients during a 1-5-years follow-up period. This was true in this series also, some degree of lowering of blood pressure being noted in 84 of 100 cases. When the blood-pressure levels of these same 100 cases were re-evaluated during the 5-9-years period we found that only 47 cases continued to have as great a lowering of blood pressure. This indicates clearly that there has been a gradual return of blood pressure towards or to the pre-operative levels in 44% of the cases in which the levels were lower during the earlier follow-up period. This trend is indicated by Table XI.

It is apparent that, when the cardiovascular status of the patient as a whole was considered in relation to the degree of lowering of blood pressure, progress of cardiovascular disease was least in those cases having the most marked lowering for the longest period of time and greatest in those having the least lowering (Table XII). This suggests that lowering of blood pressure is beneficial. It is also of interest that many of the cases showing no significant change in pressure at the end of the period of observation had cardiovascular systems which

TABLE XI—Comparison of Early and Late Effect of Operation Upon Blood Pressure Living Patients

Effect on Blood Pressure	No of Cases in 1-5 Year Period	No of Cases in 5-9 Year Period

Total	100	100

\* Diastolic blood pressure lowered 20 mm or more and to below 90

† Diastolic blood pressure lowered 20 mm or more and to below 110

‡ Diastolic blood pressure lowered 10-19 mm and to below 110

TABLE XII—Blood Pressure and Cardiovascular Status Living Patients

Late Effect of Operation on Blood Pressure	No of Cases	Cardiovascular Status 5-9 Years after Operation		
		Improved	No Change	Worse
Marked	21	81 1%	4 6%	14 3%
Moderate	13	76 9%	0 0%	23 1%
Slight	13	46 2%	23 1%	30 7%
No significant change	36	43 4%	17 8%	38 8%
Higher	17	11 7%	11 7%	76 6%
Total	100	51 0%	12 0%	37 0%

were actually in better condition than before operation, and in the majority of these cases there had been no evidence of progression of vascular disease.

FIG 1—Response to Valsalva test before and after lumbo-dorsal splanchnicectomy. Variations in blood pressure caused by reflex vasoconstriction are abolished when a large vascular area such as the splanchnic bed is denervated. These variations may be very marked, as in this case. This physiological effect of sympathectomy occurs regardless of whether the basal levels are altered or not and is well demonstrated by the Valsalva manoeuvre as in this figure. Intra-arterial blood-pressure levels are optically recorded with a Hamilton manometer before during, and after a ten second period of forced expiration. Before operation there was a sharp overshoot of blood pressure to very high levels within a few seconds after the expiratory period. After operation (shaded graph) the overshoot was abolished. It seems probable that the elimination of such reflex variations in blood pressure is partly responsible for the favourable changes in the cardiovascular system which may be noted after operation.

Slowing the rate of progress of cardiovascular disease after surgery may prove to be a very significant accomplishment. It should be remembered that most of these patients had lower average levels of blood pressure for one to five years. In addition, it may be assumed that virtually all of them had an abolition of the marked reflex vasoconstrictor response described by Wilkins *et al* (1947, 1948), and that most of them continued to have these responses greatly reduced, if not abolished, for years after the operation. This change, which can be readily demonstrated by means of the Valsalva test (Fig 1), constitutes a second physiological effect of lumbo-dorsal splanchnicectomy upon blood pressure and is not necessarily related to changes in basal levels. Examples of persistent and temporary reductions in basal blood-pressure levels are illustrated by Figs 2 and 3.

FIG 2—This case, that of a 31-year-old physician, came to hospital with rather severe hypertension, Type I. This had been discovered within a year prior to admission. His symptoms were comparatively mild, and consisted of occasional headaches, ease of fatigue, and shortness of breath. There was no evidence of cerebral damage. The eyegrounds showed grade 1 changes. The electrocardiogram was abnormal, and is reproduced in Fig 5. The heart was slightly enlarged. There was evidence of early congestive failure, as revealed by radiography of the chest and by the presence of alternation and gallop rhythm. This responded well to digitalis. The aorta was tortuous. The renal function was normal by ordinary tests. There was slight persistent albuminuria. The blood pressure fell to 135/98 on sedation. Five years after operation his general cardiovascular status was improved. His eyegrounds were unchanged. His heart was within normal limits as to size. There was no evidence of failure. He did not require digitalis. The electrocardiogram was normal (Fig 5). The aorta was tortuous. The renal function was normal and there was no albuminuria. He was asymptomatic and had carried on a very active surgical practice since operation. In the upper portion of the figure the blood-pressure levels as revealed by the postural and cold test are compared before and one year after operation. In the lower portion of the figure the levels before and five years after operation are compared. The actual levels were as follows:

	Lying	Standing	Ceiling Cold		Cold Response	
			Lying	Standing	Lying	Standing
Pre-operative	160/122	179/147	204/160	218/170	30/20	28/20
Post-operative (1 year)	103/68	114/90	120/80	132/108	26/22	26/24
Post-operative (5 years)	110/78	122/98	136/110	164/122	26/22	30/12

This case was ideally suited for surgical treatment. The effect upon the blood-pressure level was marked (see Table XI) and persistent.

In general the most favourable cases are those in the younger age groups, with narrower pulse pressures (Types I and II), who have variable blood pressures, with resting diastolic levels below 140 mm and preferably below 130 mm, with cardiovascular systems not too severely damaged, and with a satisfactory response to sedation.

FIG 3—This case, that of a 45-year-old male nurse, was admitted to hospital because of congestive heart failure. On examination he was found to have hypertension. The eyeground changes were very marked, with arterial constriction and sclerosis grade 2, haemorrhages and exudate, and papilloedema. It was therefore apparent that he had so-called malignant hypertension. There was no evidence of cerebral involvement. The heart was enlarged and the electrocardiogram was abnormal. The kidney function was normal by ordinary tests except for rather marked and persistent albuminuria. The blood pressure fell from a resting level of 202/121 to 142/86 on sedation. The resting level indicated that this patient had a wide pulse-pressure type of hypertension (Type III). These data indicated that the patient's outlook was serious. He responded well to bed rest and digitalization. Operation was performed and he recovered uneventfully. One year later he was much improved and was leading a normal existence without digitalis. His cardiovascular system was improved, as was his blood pressure. The effect of operation upon the blood pressure level was graded as slight (see Table XI). Five years after operation his general condition was still improved and was the same as that noted at the end of the first year. The blood pressure had returned toward but had not quite reached the pre-operative levels. At this time his eyegrounds showed grade 2 changes, his heart was abnormal in size and shape but normal in function. The electrocardiogram was abnormal but improved by comparison with the pre-operative tracing. The renal function was normal by ordinary tests. There was no albuminuria. The blood-pressure levels are compared in the upper portion of the figure before and 13 months after operation. In the lower graph the levels before and five years later are contrasted. The blood pressure levels during the postural and cold tests were as follows:

	Lying	Standing	Ceiling Cold		Cold Response	
			Lying	Standing	Lying	Standing
Pre-operative	202/121	226/146	246/155	250/166	26/28	20/20
Post-operative (1 year)	164/105	180/110	172/114	180/120	6/14	16/4
Post-operative (5 years)	201/127	185/130	214/140	200/150	24/22	10/18

This is an example of a worth while but less satisfactory result when compared with the case illustrated by Fig 2. The older age and presumably longer duration of the hypertension, and consequently more extensive vascular disease, are unfavourable signs. The wide

pulse pressure is also an unfavourable finding. The explanation for recurrence of hypertension following surgery is not clear. Regeneration may play a part but is not a satisfactory explanation, since the reflex response to the Valsalva manoeuvre and other stimuli may still be abolished years after operation. The status of the cardiovascular system at the time of operation appears to be equally if not more important in this connexion. Even though the blood pressure levels may be lowered to a significant degree, if they are still considerably above the normal range vascular disease progresses, and in time the blood pressure levels rise again. The more nearly the pressure approaches normal after operation the longer the respite from the disorder.

### Life Expectancy of Hypertensive Patients Comparison of non-surgically and surgically treated patients

Data reported on the life expectancy of hypertensive patients not treated surgically and observed for long periods of time are summarized in Table XIII. There is rather

TABLE XIII—Mortality Among Hypertensive Patients Treated Medically or Untreated

Author	No of Cases	Time Followed Up	Mortality
Janeway (1913)	458	1-10 years	5 years—50% 10 years—75% (53% of men 33% of women)
Blackford, Bowers, and Baker (1930)	202	5-11 years	50% (70% of men 39% of women)
Keith, Wagener and Barker (1939)	219	5-9 years	91% (93% of men 88% of women)
Rasmussen and Boe (1945)	100	6 years	52% (71% of men 43% of women)
Bechgaard (1946)	1 038	4-11 years	28% (41% of men 22% of women)

close agreement in the statistics of Janeway (1913), Blackford, Bowers, and Baker (1930), and Rasmussen and Boe (1945). About a half of their patients died during the course of some five years' observation. The mortality among men was considerably higher than among women. The findings of Keith, Wagener, and Barker (1939) and of Bechgaard (1946), however, differ widely from each other and from those of the previous authors. The Mayo group found that 91% of their patients died during a 5-9-years period of observation, the mortality for males being only slightly greater than that for females. Bechgaard reported an overall mortality of 28% during a 4-11-years period, that for men being about twice as great as for women.

It is apparent from these statistics that there is a wide variation in the mortality rates for hypertensive patients considered as groups. Further, it is obviously impossible to compare different groups of cases with each other, whether untreated or treated, unless they are divided into more comparable subgroups. In making these subgroups the numerous variables known to exist and to influence the outcome in this complex disorder should be held as constant as possible. In this way, and only in this way, can we arrive at a

reasonably accurate prognosis for a particular patient. Comparisons between such subgroups would then be of value and could be utilized to determine whether a particular therapeutic measure materially influenced the natural course of the disorder.

The first attempt to divide hypertensive patients into more comparable subgroups was made by Keith, Wagener, and Barker (1939). Their subdivision of a series of 219 patients into four groups was based upon the changes detected by a careful examination of the eyegrounds. Four grades were described, and the cases were grouped largely upon this basis. Survival curves were constructed for each group, and a material difference in prognosis for each of the groups was demonstrated. The survival curves for their four groups are reproduced in Fig. 4. We have arranged our cases into four similar groups. The survival curves for our series are also illustrated in Fig. 4. The two sets of curves are similar, and confirm their conclusion that the prognosis for hypertensive patients in the various groups differs materially. The survival rate in each of the four groups was higher in our surgically treated series. The differences observed have been subjected to statistical analysis, the results of which are summarized in Table XIV. The difference appears to be very significant for groups 2, 3, and 4, and increasingly so as the retinal changes become more severe. This suggests that the outlook for hypertensive patients has been improved by surgical therapy. It should be pointed out, however, that this subdivision into four groups, while no doubt a useful initial breakdown, permits of wide variations in the material contained within each group. When these four groups are further subdivided according to sex, age, severity of hypertension as judged particularly by the resting diastolic level, and the changes present in other vascular areas, it seems likely that the outlook for a particular patient can be assessed more accurately, and that the merits of a particular therapeutic

FIG. 4—Survival curves following splanchnicectomy. 224 cases followed 5 to 9 years, arranged according to Keith-Wagener-Barker groups and compared with their 219 cases followed 5 to 9 years. As pointed out in the text, the division of hypertensive patients into more comparable subgroups is highly desirable. The division into four groups on the basis of eyeground changes is a step in the right direction, and is probably the most important initial breakdown which can be made. It still permits of wide variations in the material contained within each group. Consequently, further divisions are needed in which other important variables are held constant. This requires a larger number of cases, however, which we will have available as our follow-up studies progress. On the basis of the data at hand it seems probable that the outlook for hypertensive patients treated surgically is improved in all stages of the disorder. The difference observed was found to be statistically very significant for groups 2, 3, and 4 (see Table XIV).

FIG 5—In this figure serial electrocardiographic tracings are recorded over a five year period. This is the case illustrated by Fig 2. The tracing immediately after operation was improved. That one year after operation was also improved, but not as much as that one week after splanchnicectomy. The tracing gradually improved and was regarded as within the normal range by the end of four years. It was still normal five years after operation.

measure may be evaluated with greater certainty. To do this will require large numbers of patients followed up for long periods of time.

TABLE XIV—Significance of the Difference Observed Between the Survival Curves following Lumbo dorsal Splanchnicectomy and those of Keith Wagener and Barker

Group	Time of Comparison*	$\chi^2$	Probability of Difference Observed being Due to Chance Alone	Significance
1	62 months	0.694	45 in 100†	Not significant Very
2	86	10.5	1 in 1,000	
3	77	18.6	1 in 100,000	
4	70	73.8	Less than 1 in 10 <sup>6</sup>	

\*When compared there were 58 of 67 survivals in the surgical and 7 of 10 in the non surgical group 1 series. The corresponding numbers for the other groups were 50 of 68 and 9 of 26 in group 2, 39 of 70 and 4 of 37 in group 3, and 20 of 39 and 1 of 146 in group 4.

†It is ordinarily assumed that any probability of occurrence of less than 5 chances in 100 is not due to chance alone.

The only other comparison which can be made at the present time is between the electrocardiograms of surgically and non-surgically treated patients. The changes observed in 125 of our patients are compared with a series of 50 non-surgically treated patients reported by Canabal, Warneford-Thomson, and White (1945). All of the cases in each group were followed up for five years or more. The differences observed in the two groups have been analysed statistically and the data are summarized in Table XV. The differences appear to

TABLE XV—A Comparison of the Electrocardiograms of Surgically Treated Patients with those of Non-Surgically or Untreated Hypertensive Patients

Series	No of Cases	Status After 5 Years or More Observation		
		Improved	No Change	Worse
Surgical (Smithwick 1948)	125	42.3%	48.8%	8.9%
Non surgical (Canabal, Warneford Thomson and White 1945)	50	10.0%	40.0%	50.0%

The observed difference between the two series is very significant  $\chi^2 = 40.8$ . The probability that the observed difference is due to chance alone is less than 1 in 10<sup>9</sup>.

be very significant, and suggest that the course of hypertensive heart disease, as judged by the electrocardiograms, has been favourably modified by surgical therapy. Serial

electrocardiograms indicating a prolonged and favourable response to operation are illustrated by Fig 5.

### Summary

It should be recognized that the series of 256 cases of continued hypertension here studied is not representative of hypertensive patients as a whole, since it does not include those in the stage of intermittent hypertension. All had reached the stage of continued hypertension and 99% had some evidence of cardiovascular disease, which was regarded as serious in about 80% of the group. They, for the most part, are patients who had not responded to other therapeutic measures available at the time of operation. In some the disorder was discovered only shortly before operation and in a very advanced state. In a few the cardiovascular changes were minimal. The patients in this group are not so seriously ill as those of Keith, Wagener, and Barker, but are probably more advanced than the other series referred to. This group of cases is probably more comparable to that of Peet and Isberg (1946, 1948), who have made

the only other late follow-up studies of a sizable series of patients treated surgically.

Our patients have been divided into various groups according to sex, age, and resting diastolic levels. They have also been divided according to the state of the cardiovascular system before operation. The mortality is indicated in the tables, and varies greatly according to the many variable factors which are present in this disorder.

The effect of operation upon the cardiovascular system has been indicated by comparing the changes in various vascular areas before with those noted five to nine years after operation with particular reference to eyegrounds, electrocardiograms, renal function, and the vascular system as a whole. The effect of splanchnicectomy upon blood pressure is discussed briefly.

It is difficult to find comparable data in the literature concerning the prognosis for hypertensive patients treated medically or untreated. Survival curves following surgical treatment are compared with those of Keith, Wagener, and Barker. The survival rate was higher in all groups in the surgically treated series. The difference observed was found to be statistically very significant for groups 2, 3, and 4. The status of the electrocardiograms in a group of surgically treated patients is compared with that of a control series reported by Canabal, Warneford-Thomson, and White. The difference observed was also found to be very significant statistically. With regard to symptoms over 90% of the patients who have so far been interviewed five to nine years after operation are improved in this respect.

Further comparison of surgically and non surgically treated cases divided into similar subgroups in which the most important variables are held constant is desirable. Until this can be done the influence and relative merits of various therapeutic measures upon the course of hypertensive cardiovascular disease cannot be evaluated with certainty. Such comparisons as can be made at this time, while admittedly inadequate, suggest that surgical treatment has favourably altered the prognosis of many patients with continued hypertension and cardiovascular disease.

I am indebted to Dr K. E. Penrod for making the statistical analyses recorded in Tables XIV and XV.

## THE SPHENOID SINUS\*

By

ARTHUR W. PROETZ, M.D.

(of St. Louis)

In scanning the literature of sinusitis one has the impression that with the sphenoid, and even more with the posterior ethmoid, it is a case of "out of sight out of mind." The maxillary and the frontal cavities are so accessible for direct observation, transillumination, x-rays, and treatment that they receive more than their share of attention. What we know of them is apt to be applied by inference to the others. To some extent this is practical, but the sphenoid has special attributes. Being of an anatomical and physiological nature they are of more than passing interest since they constitute the basis of treatment.

I shall review briefly only those anatomical characteristics which among the sinuses are peculiar to the sphenoid. It develops that most of them are

Situated in the depth of the nasal cavity out of the direct line of the air-stream, the sphenoid sinus is sheltered from cold and dust and dryness. In the normal nose only a small part of the face of the sphenoid is visible or even accessible. As to the cavity itself almost every part is in intimate contact with some structure capable of making serious trouble when disturbed.

### Structure

On examining skulls one is often impressed with the thinness of the bony walls and the intimate relations which the pneumatized cavity assumes with neighbouring structures. It is almost as though some corroding or dissolving fluid had been at work in the bone extending the cavity here and there adapting it to the contours of the surrounding nerves and vessels leaving only a mere shell of bone between. Sometimes even this disappears and the normally adjoining structure finds itself but for the thinning mucosa, within the sphenoid cavity.

There are no fewer than 15 such structures: the dura mater, the pituitary body, the optic nerve and chiasm, the cavernous sinus, the internal carotid artery, the abducens nerve, the oculo-motor nerve, the trochlear nerve, the ophthalmic nerve, the maxillary nerve, the sphenopalatine ganglion, the sphenopalatine artery, and the pterygoid canal and its nerve.

Herniations of the mucosa through dehiscences in the bone have been known to occur. They may carry the cavity of the sphenoid sinus even beyond the normal limits of the sphenoid bone. Contrast this with the maxillary sinus whose walls are relatively sturdy and accessible and whose environs are much less vulnerable.

There are histological and physiological differences as well. The inspired air passing the face of the sphenoid on its way to the pharynx misses the ostium, which lies lateral to the main current. The sphenoidal mucosa is quite thin, and being thoroughly protected from the evaporating effects

of air currents is very sparsely supplied with glands—a thing of primary importance to the surgeon.

The ostium, in any case, is likely to be a slit rather than a well-defined opening. When a high nasal obstruction occurs and there is swelling of the mucosa of the sphenoidal angle the ostium is closed. Ciliary streams within the sinus converging at the ostium are blocked and the mucus is retained. Since there are few glands and therefore scant mucus the inundation is not comparable to that which occurs in the maxillary sinus.

Unless the invading organism is especially virulent the reaction is apt to be a low-grade affair tending to chronicity if overlooked and producing a dense but relatively thin hyperplasia. Thick redundant polypoid hyperplasias do occur but the type often encountered in the maxillary antrum is the exception. In evaluating roentgenographic shadows one should remember that it is possible even for this thin membrane to be so distended by a transient oedema as to obliterate the cavity completely.

### Sinus Infections

The nature and proportion of severe sinus infections seem to depend somewhat upon climate, living conditions, and public health education. Not only do the majority of severe cases originate in communities where these are unfavourable but on the whole their incidence has fallen off materially in one's own recollection as a result of early attention to minor infections and obstructions.

There is the occasional case of fulminating suppurative sphenoiditis, acute invasive destructive threatening life. On this I shall not dwell for there is little in its diagnosis or management that is debatable. Only the prognosis has been modified in recent years by the advent of the sulphonamides and the antibiotics. The management of anything less than such an emergency seems to me to call first for consideration of the ultimate recovery of physiological function. Under such conditions eradication of 'pyogenic' membranes is apt to impede drainage permanently and should be the last instead of the first resort.

It is necessary to distinguish between an abscess and a pus-filled sinus, a distinction not usually made in years past. The abscess is a collection of infectious material lying in an adventitious cavity requiring evacuation and obliteration to return the tissues to normal. The sinus on the other hand is an infected hollow anatomical structure having functioning parts temporarily deranged but capable of restoration. Obliteration of such a structure approximates normality no more than does the amputation of an arm or a leg although it may become necessary in either case for special reasons.

In the older literature treatment does not take into account the physiological processes by means of which a sinus protects itself and this is still true of many contemporary textbooks. Most of these are only rewritten from older textbooks and though the author may have the courage to introduce new ideas he is somehow reluctant to discard old ones however faulty. On the whole, treatment of sphenoiditis is suggested tentatively in the textbooks with the reservation that if this fails measures more and more drastic must be applied. In the light of present knowledge it is clear that if the treatment suggested did not actually prevent recovery it could only retard it at best. At worst it produced a situation requiring the most drastic measures.

To clarify, Skillern (1923) relates that "a long cotton-carrier saturated with strong adrenaline-cocaine solution is introduced into the ostium and allowed to remain several minutes until the mucosa around the opening is shrunken, thereby enlarging the ostium." This is carried out daily with subsequent irrigation. It is known now that the

\*Read in opening a discussion in the Section of Otorhinolaryngology at the Annual Meeting of the British Medical Association Cambridge 1948.

two mortal enemies of ciliary activity are cocaine and epinephrine and that their daily application in strong solution through the ostium, whence they could run to the floor must have effectively prevented the very drainage for which they were applied, a function at which the cilia are much better than we are

### Drainage

While on the subject of drainage reference may be made to the older and some of the newer literature in regard to surgical openings. We are cautioned to make these in dependent portions for drainage, smoothing the edges and leaving no ridges to retain secretions. This reckons without the cilia, which keep right on emptying mucus through the ostium as long as possible, and further overlooks the fact that for one-third of our lives we are lying down. We know now that nature does not depend upon gravity for drainage.

Newer methods are based on the better understanding of the cilia and their importance and upon the assurance, given long ago by Wright and Smith (1914a) and scarcely heeded by anyone at the time, that in chronic rhinitis "there is an increase in the volume of the connective tissue, but this is often more apparent than real. There can usually be plainly seen in the neighbourhood of blood vessels new connective-tissue cells, and the periosteum is much thicker in some places than in others, but the bulk of the stroma increase is due not to proliferation of the connective tissue alone, but to the dilatation of the lymph spaces and the filling of the meshes of the stroma with serum and corpuscular elements, lymphocytes, and polynuclears. The coagulation of the fibrin incidental to the fixation of the specimen for examination in sections makes a mass of fibrinous threads indistinguishable from the real fibrils of the connective-tissue cells except by special staining, but when this is resorted to the scantiness of new connective-tissue cells and their fibrils will be noted when compared to the general increase in bulk."

Searching for this passage, I was dumbfounded to find also a reference to something which I thought was original with me 20 years later. "There is one observation to be noted in regard to the oedematous and granulomatous fragments of mucosa removed from long-standing chronic inflammation of the sinuses, and that is the persistence of the cilia on the surface. Widespread and extreme lesions may exist in the subepithelial stroma, but the delicate cilia of the one- or two-layered columnar epithelium remain in tissue removed from the sinuses" (Wright and Smith, 1914b). Once more in the deep shadow of a library shelf we find what we had thought was something new under the sun.

### New Procedures

These newer conceptions require changing of the rules of sinus treatment and sinus surgery. Since the sphenoid is rather badly situated for the old procedures and almost ideally for the new, let us outline some of the latter here.

Vasoconstrictors should be chosen for their freedom from any restraining action on the cilia, for their freedom from secondary vasodilatation effects, and, if introduced into the sinuses, for their freedom from systemic effects.

Cocaine is taboo for anything but analgesia, epinephrine for anything but haemostasis.

Antiseptics are of small value, partly because they impede ciliary activity, more particularly because they do not reach the infection which is in the glands and tissues of the submucosa.

Any solution employed in the nose should be relatively isotonic and neutral in reaction.

Any surgical opening short of the radical obliterative operation should be (a) as much as possible out of the direct air-stream, (b) as small as practicable, to prevent drying out the

interior of the cavity, and (c) as cleanly cut as possible to avoid exuberant granulations and closing.

All these measures are far away from the old idea of obliteration and are directed towards physiological recovery. Let us apply them to the sphenoid. Sphenoiditis is not necessarily characterized by pus. Pus may be absent or so scant as to be practically undetectable. Sometimes, though present in quantity, it may discharge only intermittently and thus be overlooked by the examiner. Symptoms attributable to low-grade, acute, and chronic sphenoiditis have been well and frequently described. They range from simple demonstrable reactions of inflammation to pain, headache, and mental confusion. Collateral symptoms are those arising from the irritation of any of the structures mentioned above which lie in relation to the cavity. Commonly, though not always, they subside with the disappearance of the sphenoiditis.

Since minor and indefinite derangements of the sphenoidal mucosa can give rise to annoying and disabling symptoms it is important that the measures adopted should restore the tissues to function and not leave new abnormalities in their wake. This can be accomplished in the majority of cases by the application of solutions by the "displacement" principle. The sphenoid is fortunately situated in this respect, since, with the head in the inverted position, it lies at the bottom of the cavity with its ostium uppermost.

The arrangement of the tissues about the ostium is such that most of the distensible elements are components of the mucosa on the nasal side, the sphenoidal membrane being much thinner and relatively free of blood spaces. For this reason application of vasoconstrictors to the face of the sphenoid about the ostium is usually sufficient to open it without having to penetrate it. If this is not the case, the interior is still accessible through the displacement manoeuvre, since it is possible with the permitted negative pressure to withdraw a small part of the contained air and thus ensure the introduction of some of the fluid.

If a mild vasoconstrictor—for example, 0.25% ephedrine sulphate or 2-aminohexane sulphate—is introduced every second day drainage is maintained over a period of time which is comparable to surgical drainage—in fact better since it promotes emptying in the normal way.

Bearing in mind Wright's description of the cytological conditions it is not surprising that the membrane tends to heal to throw off its infection, and to return to normal which it commonly does. Whether or not some excess of fibrotic tissue remains is unimportant so long as the patient is symptom-free. It is seldom necessary to remove contained secretions by positive irrigation or other means. With the ostium open and the cilia working the sinus takes care of itself. Since aqueous solutions remain in the sinus after displacement for 10 or 12 hours continuous drainage is ensured.

If the reaction in the tissues has reached a point where it is irreversible and the method fails, then surgical drainage must be established.

### Surgical Intervention

Adhering still to physiological principles, a narrow longitudinal opening is made as close to the septum (or intersinus wall) as possible. Its width is only that of sharp-biting punch forceps (for it is important to keep margins smooth and clean) and it is as long as can conveniently be made in that portion of the bone which cuts easily. Prolonging the operation downward into the thicker, resistant bone does not add to its effectiveness but increases the likelihood of early closure by stimulating proliferation. There is much less tendency to close than exists after

general destruction of the face with its ostium. Nature makes every attempt to close any opening, while we persist in trying to thwart her.

This narrow opening as described will accomplish anything that the larger one will do. It permits access for observation, ventilation, drainage, and irrigation, and prevents the desiccation of the interior which results in the destruction of cilia and the metaplasia of the epithelium—in irreversible change which may start up disagreeable symptoms of its own.

The operation is comparable to a so-called "antrum window," which is effective because it lies away from the air-stream and leaves the ostium intact. It is of course not applicable to sinuses obliterated by large cysts and abscesses, nor is it designed for exploratory purposes such as the diagnosis of tumours, aneurysms, and the like. It would not apply to most of the type of cases described a few years ago by Pickworth and Graves, in which the bone had been deeply involved and the infection had reached the meninges, or to those discussed in Turner and Reynolds's classical monograph on intracranial invasions. For such the emergency suggests its own rules, fortunately they are the exception.

Collateral problems surrounding the sphenoid occur to one, such as its part in the causation of headaches, neuralgias, intracranial lesions, and retrobulbar neuritis. Each of them has been the subject of much debate, and I am not sure that I could add anything to what has been said many times on both sides of the Atlantic.

In the time available it seemed preferable to emphasize those physiological factors which may alter our conception of what is desirable in sinus treatment and open the way to better end-results in sinus surgery. My own approaches are of secondary importance. If this review has helped to awaken fresh interest in the subject or suggested a fresh point of view it will have served its purpose.

—— (1914b) *Ibid.*, p. 128.

To mark the beginning of the National Health Service the Minister of Health attended various ceremonies in Lancashire on July 5. Speaking at Preston Mr. Bevan said that he wanted to thank all those men and women—in local government, in voluntary hospitals, in insurance committees, in nursing associations, and in all those other bodies and organizations—which had had the job to do in the past and had done it so well. They were handing over to him such that was a good going concern, with good ready-made assets with which to start, and so making the task easier. "We are not changing the old services because they were bad, we are changing them to make good services better and more available to all." He would also like to thank all those who had worked unremittingly during the last two years in framing the new scheme. Among them were the representatives of the professions who had helped with consultations and administrative arrangements, especially the chemists, ophthalmic surgeons and opticians, whose willing and constructive co-operation had been most valuable in working out a better scheme than would otherwise have been possible. He would particularly mention the staffs of insurance committees, who now passed executive councils and who had had to carry a very heavy burden, the various local professional committees, those who had worked on preparatory committees, such as the three presided over by Sir Will Spens, the Pharmaceutical Working Party under Mr. W. H. H. and the Dental Estimates Board and its officers. There were some doctors reported to be telling some of their patients that they would accept them as paying patients but not under the National Health Service. Such conduct was of course a complete abuse of the doctor's right of free choice of patient, and doctors guilty of it would be condemned by their colleagues as a disgrace to their profession. All could help the new scheme by co-operation, by coaching the Service with the determination to make it work, and by not rushing for treatment which was not urgent in the early days of the scheme.

## THE SURGICAL ANATOMY OF THE PAROTID GLAND\*

BY

HAMILTON BAILEY, F.R.C.S., F.A.C.S., F.I.C.S.  
F.R.S.E.d.

Surgeon Royal Northern Hospital General Surgeon  
Metropolitan Ear Nose and Throat Hospital

Gray, Buchanan, Piersol, Cunningham, Quain, and Morris are among an elect company whose names strike a most familiar note in the mind of every member of the profession. One or other of their classic books recalls the early years of our professional studies. Rightly we regard our anatomical bibles with profound respect, the more so perhaps, because anatomy, the basic subject of the curriculum, can be likened unto the law of the Medes and Persians.

Because of stereotyped descriptions in the anatomical textbooks we envisage the normal parotid gland as being possessed of a plateau-like superficial surface and a deep surface with prolongations into vulnerable and inaccessible recesses. For the same reason (strengthened by personal experience in the dissecting-room) the profession believes that in the midst of the gland lies the seventh cranial nerve, so intimately incorporated in salivary tissue that to display the nerve trunk, its two divisions, and, above all, its fine branches requires days of dissection by someone upon whom the mantle of John Hunter has fallen.

Little wonder, then, that general practitioners, physicians and surgeons alike are steeped in the doctrine promulgated by that prince of surgical anatomists Sir Frederick Treves—"It follows from the complex relations of the parotid that its entire removal as a surgical procedure is an anatomical impossibility."

In 1937, after coming across its superficial lobe accidentally during the course of an operation upon the parotid gland and subsequently being inspired by the anatomical studies of McWhorter (1917), I came to the conclusion that the parotid was a bilobed structure, and that the facial nerve lay not in the gland but between its two lobes, in short, that the facial nerve might be regarded as the meat within a parotid sandwich (Fig. 1). No other secretory gland, I argued, has an important motor nerve† running through it, and no other secretory gland has lymphatic nodes within its parenchyma. Surely both the nerve and the lymphatic nodes are extracapsular, just in the same way as lymphatic nodes lie tucked between the opposing capsule-covered surfaces of the buccal and cervical lobes of the submaxillary salivary gland.

Although there are considerable variations in the position of the nerve within the parotid gland for practical purposes it may be stated that much more often than not the facial nerve lies between a comparatively large superficial lobe and a variably sized deep lobe, the two being connected by an isthmus. It is on this anatomical concept that the operations of superficial lobectomy and complete parotidectomy are rendered practicable, consequently the

FIG. 1—Diagrammatic conception of a coronal section through the parotid gland, showing the branches of the facial nerve sandwiched between the superficial and deep lobes.

\*Part of an address delivered before the Assembly of the International College of Surgeons in Rome on May 19, 1948.

†A possible exception is the recurrent laryngeal nerve, which, according to Berlin, traverses the thyroid gland in 7% of cases.

two mortal enemies of ciliary activity are cocaine and epinephrine and that their daily application in strong solution through the ostium, whence they could run to the floor, must have effectively prevented the very drainage for which they were applied, a function at which the cilia are much better than we are

### Drainage

While on the subject of drainage reference may be made to the older and some of the newer literature in regard to surgical openings. We are cautioned to make these in dependent portions for drainage, smoothing the edges and leaving no ridges to retain secretions. This reckons without the cilia, which keep right on emptying mucus through the ostium as long as possible, and further overlooks the fact that for one-third of our lives we are lying down. We know now that nature does not depend upon gravity for drainage.

Newer methods are based on the better understanding of the cilia and their importance and upon the assurance, given long ago by Wright and Smith (1914a) and scarcely heeded by anyone at the time, that in chronic rhinitis "there is an increase in the volume of the connective tissue, but this is often more apparent than real. There can usually be plainly seen in the neighbourhood of blood vessels new connective-tissue cells, and the periosteum is much thicker in some places than in others, but the bulk of the stroma increase is due not to proliferation of the connective tissue alone, but to the dilatation of the lymph spaces and the filling of the meshes of the stroma with serum and corpuscular elements, lymphocytes, and polynuclears. The coagulation of the fibrin incidental to the fixation of the specimen for examination in sections makes a mass of fibrinous threads indistinguishable from the real fibrils of the connective-tissue cells except by special staining, but when this is resorted to the scantiness of new connective-tissue cells and their fibrils will be noted when compared to the general increase in bulk."

Searching for this passage, I was dumbfounded to find also a reference to something which I thought was original with me 20 years later. "There is one observation to be noted in regard to the oedematous and granulomatous fragments of mucosa removed from long-standing chronic inflammation of the sinuses, and that is the persistence of the cilia on the surface. Widespread and extreme lesions may exist in the subepithelial stroma, but the delicate cilia of the one- or two-layered columnar epithelium remain in tissue removed from the sinuses" (Wright and Smith, 1914b). Once more in the deep shadow of a library shelf we find what we had thought was something new under the sun.

### New Procedures

These newer conceptions require changing of the rules of sinus treatment and sinus surgery. Since the sphenoid is rather badly situated for the old procedures and almost ideally for the new, let us outline some of the latter here.

Vasoconstrictors should be chosen for their freedom from any restraining action on the cilia, for their freedom from secondary vasodilatation effects, and, if introduced into the sinuses, for their freedom from systemic effects.

Cocaine is taboo for anything but analgesia, epinephrine for anything but haemostasis.

Antiseptics are of small value, partly because they impede ciliary activity more particularly because they do not reach the infection, which is in the glands and tissues of the submucosa.

Any solution employed in the nose should be relatively isotonic and neutral in reaction.

Any surgical opening short of the radical obliterative operation should be (a) as much as possible out of the direct air-stream, (b) as small as practicable, to prevent drying out the

interior of the cavity, and (c) as cleanly cut as possible to avoid exuberant granulations and closing.

All these measures are far away from the old idea of obliteration and are directed towards physiological recovery. Let us apply them to the sphenoid. Sphenoiditis is not necessarily characterized by pus. Pus may be absent or so scant as to be practically undetectable. Sometimes, though present in quantity, it may discharge only intermittently and thus be overlooked by the examiner. Symptoms attributable to low-grade, acute, and chronic sphenoiditis have been well and frequently described. They range from simple demonstrable reactions of inflammation to pain, headache, and mental confusion. Collateral symptoms are those arising from the irritation of any of the structures mentioned above which lie in relation to the cavity. Commonly, though not always, they subside with the disappearance of the sphenoiditis.

Since minor and indefinite derangements of the sphenoidal mucosa can give rise to annoying and disabling symptoms it is important that the measures adopted should restore the tissues to function and not leave new abnormalities in their wake. This can be accomplished in the majority of cases by the application of solutions by the "displacement" principle. The sphenoid is fortunately situated in this respect, since, with the head in the inverted position, it lies at the bottom of the cavity with its ostium uppermost.

The arrangement of the tissues about the ostium is such that most of the distensible elements are components of the mucosa on the nasal side, the sphenoidal membrane being much thinner and relatively free of blood spaces. For this reason application of vasoconstrictors to the face of the sphenoid about the ostium is usually sufficient to open it without having to penetrate it. If this is not the case, the interior is still accessible through the displacement manoeuvre, since it is possible with the permitted negative pressure to withdraw a small part of the contained air and thus ensure the introduction of some of the fluid.

If a mild vasoconstrictor—for example, 0.25% ephedrine sulphate or 2-aminoheptane sulphate—is introduced every second day drainage is maintained over a period of time which is comparable to surgical drainage—in fact better since it promotes emptying in the normal way.

Bearing in mind Wright's description of the cytological conditions it is not surprising that the membrane tends to heal, to throw off its infection, and to return to normal which it commonly does. Whether or not some excess of fibrotic tissue remains is unimportant so long as the patient is symptom-free. It is seldom necessary to remove contained secretions by positive irrigation or other means. With the ostium open and the cilia working the sinus can take care of itself. Since aqueous solutions remain in the sinus after displacement for 10 or 12 hours continuous drainage is ensured.

If the reaction in the tissues has reached a point where it is irreversible and the method fails, then surgical drainage must be established.

### Surgical Intervention

Adhering still to physiological principles, a narrow longitudinal opening is made as close to the septum (or the intersinus wall) as possible. Its width is only that of sharp-biting punch forceps (for it is important to keep the margins smooth and clean) and it is as long as can conveniently be made in that portion of the bone which cuts easily. Prolonging the operation downward into the thicker, more resistant bone does not add to its effectiveness but increases the likelihood of early closure by stimulating proliferation. There is much less tendency to close than exists after the

general destruction of the face with its ostium. Nature makes every attempt to close any opening, while we persist in trying to thwart her.

This narrow opening as described will accomplish anything that the larger one will do—it permits access for observation, ventilation, drainage, and irrigation, and prevents the desiccation of the interior which results in the destruction of cilia and the metaplasia of the epithelium—an irreversible change which may start up disagreeable symptoms of its own.

The operation is comparable to a so-called "antrum window," which is effective because it lies away from the air-stream and leaves the ostium intact. It is of course not applicable to sinuses obliterated by large cysts and abscesses, nor is it designed for exploratory purposes such as the diagnosis of tumours, aneurysms, and the like. It would not apply to most of the type of cases described a few years ago by Pickworth and Graves, in which the bone had been deeply involved and the infection had reached the meninges, or to those discussed in Turner and Reynolds's classical monograph on intracranial invasions. For such the emergency suggests its own rules, fortunately they are the exception.

Collateral problems surrounding the sphenoid occur to one, such as its part in the causation of headaches, neuralgias, intracranial lesions, and retrobulbar neuritis. Each of them has been the subject of much debate, and I am not sure that I could add anything to what has been said many times on both sides of the Atlantic.

In the time available it seemed preferable to emphasize those physiological factors which may alter our conception of what is desirable in sinus treatment and open the way to better end-results in sinus surgery. My own approaches are of secondary importance. If this review has helped to awaken fresh interest in the subject or suggested a fresh point of view it will have served its purpose.

To mark the beginning of the National Health Service the Minister of Health attended various ceremonies in Lancashire on July 5. Speaking at Preston Mr. Bevan said that he wanted to thank all those men and women—in local government, in voluntary hospitals, in insurance committees, in nursing associations, and in all those other bodies and organizations—which had had the job to do in the past and had done it so well. They were handing over much that was a good going concern, with good ready-made assets with which to start, and so making the task easier. "We are not changing the old services because they were bad, we are changing rather to make good services better and more available to all." He would also like to thank all those who had worked unremittingly during the last two years in framing the new scheme. Among them were the representatives of the professions who had helped with regulations and administrative arrangements, especially the chemists and ophthalmic surgeons and opticians, whose willing and constructive co-operation had been most valuable in working out a better scheme than would otherwise have been possible. He would particularly mention the staffs of insurance committees, who now passed to executive councils and who had had to carry a very heavy burden, the various local professional committees, those who had served on preparatory committees, such as the three presided over by Sir Will Spens, the Pharmaceutical Working Party under Mr. W. Penman and the Dental Estimates Board and its officers. There were some doctors reported to be telling some of their patients that they would accept them as paying patients but not under the National Health Service. Such conduct was of course a complete abuse of the doctor's right of free choice of patient, and doctors guilty of it would be condemned by their colleagues as a disgrace to their profession. All could help the new scheme by co-operation, by approaching the Service with the determination to make it work well, and by not rushing for treatment which was not urgent in the early days of the scheme.

## THE SURGICAL ANATOMY OF THE PAROTID GLAND\*

BY

HAMILTON BAILEY, FRCS, F.A.C.S., F.I.C.S.  
FRSEd

Surgeon, Royal Northern Hospital. General Surgeon,  
Metropolitan Ear, Nose and Throat Hospital.

Gray, Buchanan, Piersol, Cunningham, Quain, and Morris are among an elect company whose names strike a most familiar note in the mind of every member of the profession—one or other of their classic books recalls the early years of our professional studies. Rightly we regard our anatomical bibles with profound respect, the more so, perhaps, because anatomy, the basic subject of the curriculum, can be likened unto the law of the Medes and Persians.

Because of stereotyped descriptions in the anatomical textbooks we envisage the normal parotid gland as being possessed of a plateau-like superficial surface and a deep surface with prolongations into vulnerable and inaccessible recesses. For the same reason (strengthened by personal experience in the dissecting-room) the profession believes that in the midst of the gland lies the seventh cranial nerve, so intimately incorporated in salivary tissue that to display the nerve trunk, its two divisions, and, above all, its fine branches requires days of dissection by someone upon whom the mantle of John Hunter has fallen.

Little wonder, then, that general practitioners, physicians, and surgeons alike are steeped in the doctrine promulgated by that prince of surgical anatomists Sir Frederick Treves—"It follows from the complex relations of the parotid that its entire removal as a surgical procedure is an anatomical impossibility."

In 1937, after coming across its superficial lobe accidentally during the course of an operation upon the parotid gland and subsequently being inspired by the anatomical studies of McWhorter (1917), I came to the conclusion that the parotid was a bilobed structure, and that the facial nerve lay not in the gland but between its two lobes, in short, that the facial nerve might be regarded as the meat within a parotid sandwich (Fig. 1). No other secretory gland, I argued, has an important motor nerve† running through it, and no other secretory gland has lymphatic nodes within its parenchyma. Surely both the nerve and the lymphatic nodes are extracapsular, just in the same way as lymphatic nodes lie tucked between the opposing capsule-covered surfaces of the buccal and cervical lobes of the submaxillary salivary gland.

Although there are considerable variations in the disposition of the nerve within the parotid gland, for practical purposes it may be stated that much more often than not the facial nerve lies between a comparatively large superficial lobe and a variably sized deep lobe, the two being connected by an isthmus. It is on this anatomical concept that the operations of superficial lobectomy and complete parotidectomy are rendered practicable, consequently the

FIG. 1—Diagrammatic conception of a coronal section through the parotid gland, showing the branches of the facial nerve sandwiched between the superficial and deep lobes.

\*Part of an address delivered before the Assembly of the International College of Surgeons in Rome on May 19, 1948.

†A possible exception is the recurrent laryngeal nerve, which, according to Berlin, traverses the thyroid gland in 7% of cases.

following description of the surgical anatomy of the parotid gland may prove helpful

The facial nerve emerges from the base of the skull at the stylo-mastoid foramen. After a course of approximately  $1\frac{1}{2}$  in (1.25 cm) it appears to plunge into the deep aspect of the gland a little below its middle. Actually it comes to lie in a groove on the under surface of the superficial lobe—viz,  I have noted repeatedly that the main trunk of the nerve can be separated by blunt dissection from the mobilized gland, aided here and there, in certain cases, by the sharp dissection of some fibrous bands. The main nerve trunk approaches the parotid isthmus from behind, and on reaching the isthmus divides into an upper temporo-facial branch which passes above the isthmus and a lower cervico-facial branch which passes below it (Fig 2)

FIG 2—The disposition of the temporo-facial and cervico-facial divisions of the facial nerve as they embrace the isthmus

Because of the relatively small size of the deep lobe, outlying subdivisions of the nerve—i.e., the pes anserinus—rest between the superficial lobe and the masseter muscle. Particularly from a surgical point of view, the temporo-facial division, which is often the larger of the two divisions, is the more important.

In a number of instances, after the two primary divisions of the nerve have embraced the isthmus they are connected at a varying distance in front of the isthmus by one or more anastomotic twigs (see Fig 2). No doubt this accounts for some cases of unexpected late recovery of partial facial paralysis following parotidectomy.

**The Isthmus**—This is variable. Sometimes it is relatively broad, even so, the primary divisions of the facial nerve seem always to embrace it.

**The Superficial Lobe**—This also varies in size and shape. Large superficial lobes often extend as much as 2 in (5 cm) downwards into the neck (Fig 3). On scores of occasions in the course of excision of adherent tuberculous cervical nodes situated in the upper third of the neck I have found it necessary to resect a portion of the cervical prolongation of the parotid gland. In a boy of 9, referred for operation because tuberculous cervical adenitis had failed to resolve, the swelling proved to be a mixed tumour situated in the cervical prolongation of the parotid gland, which extended so far downwards as to cause the swelling to be truly cervical.

**The Deep Lobe**—I have learnt to segregate deep lobes into two categories—the “knob” and the “rabbit warren”.

**The “Knob”**—In approximately 40% of cases the deep lobe is relatively small, ovoid in shape, and overlies the base of the condylar process (Fig 4). It has been argued that if the tumour has been removed satisfactorily by superficial lobectomy it is inconsistent with radical surgery to leave behind a piece of the parotid gland (the deep lobe), even if this knob is presumed to contain normal tissue. To this I rejoin, “Quite so”, but (a) even the removal of the knob causes renewed venous haemorrhage from what I take to be radicles of the posterior facial or the internal maxillary veins, and (b) until further dissection has been performed it is sometimes uncertain whether the deep lobe is in truth strictly of the “knob” variety.

**The “Rabbit Warren”**—Contiguous with the deep surface of the deep lobe is a prolongation that plunges behind the posterior border of the mandible (Fig 5) towards the styloid process, which it surrounds. The most formidable possibility is that in the depths of the warren the deep lobe is adherent to the jugular vein near its bulb. It is for this reason more than for any other that the operator can give a sigh of relief that an exacting operation is virtually completed when he is convinced that a deep lobe

FIG 3—Superficial lobe of the parotid gland with a cervical extension

FIG 4—Deep lobe Variety A the “knob”

FIG 5—Deep lobe Variety B the “rabbit warren”

consists entirely of normal parotid tissue. After leaving deep lobes, including undoubted “rabbit warrens,” *in situ* many times I am still amazed by the fact that a salivary fistula following superficial lobectomy is conspicuous by its absence.

**Stensen's Duct**—My experience of dissecting this structure in the living is at variance with what is depicted in works on anatomy. In over 80% of cases Stensen's duct is a rounded structure no larger than a fine hypodermic needle. In order to display the pes anserinus, after incising the parotid fascia longitudinally I employ transverse “haemostat dissection” (Fig 6) similar to that so well known in connexion with clearing a vein before its cannulization. By this procedure a number of thread-like structures are isolated, all cross the masseter muscle transversely. It is usually impossible to identify any one of them as the parotid duct until bisection of the isthmus (a much later step of the operation) has been carried out. Cautiously I can recall having displayed a goose-quill-like duct similar to that described in

FIG 6—Haemostat dissection

illustrated in works on anatomy, and only once have I seen a so-called parotid (accessory parotid gland), which one gathers from anatomical illustrations should be a regular appendage of Stensen's duct. McCormack and his co-workers (1945) found Stensen's duct to be duplicated in 7% of cases.

### Results of Parotidectomy

I have performed parotidectomy 77 times. In 54 cases superficial lobectomy or total parotidectomy has been performed, in the remainder extracapsular resection of a tumour was carried out. Superficial lobectomy or total parotidectomy was undertaken

For parotid tumour	45 cases
For sialactasia	6 cases
For tuberculous parotid lymphadenitis with sinuses	2 cases
For Boeck's sarcoid	1 case

In 17 cases the tumour was a recurrent one, in one case it had recurred four times after various operative procedures, and in two it had recurred twice. A number of the patients had received radiotherapy without benefit.

In six instances the patient had palpably enlarged cervical lymph nodes, these were excised either at the time of the parotidectomy or at a separate session. In five of the six cases the invasion of the nodes by the tumour was confirmed histologically. In all these five patients further metastasis has occurred, from which four of them have died. In the sixth obviously enlarged lymph nodes were (unexpectedly) reported upon as being inflammatory, and this patient, who had combined total parotidectomy and excision of cervical lymph nodes, is alive and well nine years later.

The original case of superficial lobectomy was Mrs E R, aged 65, and the operation was performed in February, 1937. In 1948 she was admitted to a municipal hospital with carcinoma of the stomach and metastases in the liver. I had seen her a year previous to this, and then she was well and without any sign of a recurrence of the parotid tumour.

All the patients who have had superficial lobectomy or complete parotidectomy performed have been followed up, and, with the exception of one who died accidentally and those who had secondary deposits at the time of the operation, all, including the recurrent cases, have been traced, been examined, and been found to be cured of their neoplasm for varying periods up to 10 years. In 80% of cases the report on the histologically variegated neoplasm, about which there is so much pathological controversy, can be summarized as "mixed parotid tumour." In a few instances the pathologist specifically stated that the tumour was a carcinoma. In three examples the tumour was found to be an adenolymphoma.\*

As for the integrity of the seventh nerve, in two patients no attempt was made to preserve it, because in one the nerve had been cut at a previous operation performed elsewhere and in the other the neoplasm (which proved to be an adenolymphoma) was so extensive and friable that the anatomy of the region was confused. Of the remaining patients over 40% had temporary facial palsy lasting for varying periods up to one year. Only five of these showed signs of facial muscular weakness after a year—but none of them are seriously inconvenienced by it. One patient has paralysis of the temporo-facial division, but by a fortunate coincidence she is the possessor of a glass eye on that side—the eye having been removed for an accident in childhood. This patient by reason of the glass eye, although

an intelligent woman, is not aware of the fact that she cannot approximate her left eyelid. In two patients on whom the operation was performed less than a year ago full recovery of the facial nerve is improbable. In one of these an immense tumour displaced the nerve medially at the stylomastoid foramen, and although the branches are intact the nerve may be damaged at its exit from the skull.† In the other the cervico-facial division entered a very large tumour which had been removed elsewhere a year previously, and I cut this division deliberately.

### Envoy

In all instances before carrying out parotidectomy I warn the patient that the integrity of the seventh nerve cannot be guaranteed and a degree of facial palsy must be expected for several months. I am thankful to say that I can now sound this warning less loudly than in time past. Moreover, I am relieved to find that in cases of parotid tumours the advice to have a large part or all of the parotid gland removed is to-day less at variance with world opinion than it was even a year or two ago.

Old beliefs die hard, and the misconceptions to which I referred (Bailey, 1947) are by no means dead, but, as a result of this follow-up, dead are my earlier beliefs and fears that my days would be darkened by disconsolate, doleful individuals whom I had hideously deformed by carrying out parotidectomy on unselected cases, particularly when operative treatment had been discouraged or stated to be definitely contraindicated by experienced general practitioners and, in some instances, by front-rank surgeons. Dead, too (or at any rate comatose), are those disturbing thoughts of standing in the witness-box pilloried by the prosecuting counsel who, holding aloft a pre-operative photograph, exhorts the jury to "look upon this picture, and on this"—my patient. In only one instance have these trepidations been vindicated even in a very mild degree.

The patient was a man, aged 34, whose obvious parotid tumour, which he said was getting bigger, added asymmetry to a face that could never have been his fortune. None the less, after removal of a tumour of a deep lobe which surrounded the styloid process, relentlessly he assured me that as the tumour had given him no trouble he would rather have kept it than be compelled to greet his staff and customers with a unilateral smile. Owing to the difficult nature of the operation I was convinced that in his case the paralysis would be permanent. Before recommending Lodge's operation for facial palsy I sent the patient to Dr Yealland, who advised waiting until 12 months had passed. This was the only patient who did not attend the follow-up I organized for the purpose of writing this review. All the other patients came, some from great distances—e.g., the North of England and Wales. Eventually, however, after five requests he condescended to call (his office being situated five minutes from Harley Street). The affected facial nerve was functioning perfectly.

"All hooley"—a descriptive term not yet in the authors' and writers' codex—succinctly conveys the impression regarding parotidectomy with preservation of the facial nerve that was gained by candidates for the Scottish and Irish as well as the English Fellowship at instructional classes in 1947. I am glad to find that, thanks to the testimony of my former house-surgeons and postgraduates, this teaching is being modified.

Regarding the pure anatomy of the facial nerve, so far as I have ascertained, Barry Anson, professor of anatomy in the Northwestern University of Chicago, whose contributions on applied anatomy are so helpful to surgeons, stands alone among English-speaking anatomists in teaching that the parotid gland is a bilobed structure with the facial nerve running between the lobes. Morris's is the only

† Since writing this, the patient has been re-examined, and the function of the seventh nerve is returning (10 months after the operation).

\* All the patients were elderly men. An adenolymphoma, in distinction to all other tumours of the parotid gland, is radio-insensitive, but clinically there is no method of distinguishing this tumour from others. A radiotherapeutic test would probably segregate these cases.

textbook in English that makes any mention of the bilobed conception, and in the 1942 edition McWhorter's (1917) paper is quoted. On the other hand, the French school of anatomists have long accepted the newer teaching, and in their standard textbook (Rouviere, 1943) the account of the parotid salivary gland is replete with a description of the facial nerve lying between a superficial and a deep lobe. In this connexion it should be emphasized that the American surgeon McWhorter (1917) admitted that he derived his ideas from the French surgeon Gregoire (1912).

Masterly sharp dissection with a knife that is deftly honed at frequent intervals is a heritage of which members of the Anatomical Society of Great Britain and Ireland are justly proud. To display the arborescing facial nerve by cutting formalin-hardened, dehydrated if not desiccated salivary tissue calls for much honing and great skill. I believe that if the supple parotid gland of a fresh subject was distended by injecting an appropriate blue-stained fluid into Stensen's duct, after employing the knife to disengage the peri-parotid fascia and to free the excised mastoid process with the sterno-mastoid muscle attached, the scalpel could be laid aside, and under these conditions, by haemostat and blunt dissection only, the main trunk of the facial nerve could be followed to its bifurcation and further without incising any (blue-stained) salivary tissue.

I am deeply indebted to Dr L. R. Yealland for examining the muscle reactions and accurately prognosticating in a number of instances where recovery from facial palsy was doubtful, to Professor Anson and his pupils for their encouraging anatomical substantiation of the bilobed structure of the parotid gland, to Mr C. Eisinger for great assistance in translating foreign works on anatomy, and to Dr Donald Teare for his careful histological study of the tumours I have removed.

Hull Royal Infirmary was founded on March 22, 1781, and received its first patients in September of the following year. To mark the transition which took place on July 5 the Managing Committee has issued a handsomely produced booklet which has been prepared by Mr K. J. Lowson. This tells the story of the Infirmary from its foundation to the present day and includes brief biographical notes on all the members of the honorary medical staff. Also included in the booklet are pictures of the hospital in 1784 and in 1850 and there are photographs of the present and past honorary staffs.

## ACUTE URAEMIA

BY

S. G. ZONDEK, M.D.

(From the Department of Internal Medicine of the Hadassah Municipal Hospital Tel-Aviv)

Extrarenal uraemia—or “prerenal uraemia” according to Fishberg (1939) and “renal anoxia” according to Macgrath *et al.* (1945)—is probably the most frequent form of acute uraemia (Zondek, 1944, 1946, Macgrath *et al.*, 1945). This view is supported by the results referred to in this paper.

Extrarenal uraemia is a non-specific body-reaction—i.e., a pathological process met with in entirely different diseases. The uraemia in question is called “extrarenal” (other possible terms will be discussed later), as it occurs in diseases not primarily involving the kidneys and in patients who may not have previously suffered from kidney trouble. The renal failure in these cases seems to be of a functional nature, another, and essential, characteristic is its association with extrarenal azotaemia, a process caused by increased endogenous breakdown of protein which can be diagnosed (Zondek, 1944, 1946) by symptoms such as an increase of non-protein nitrogen in the blood in addition to a dissociation of the urea-sodium-chloride excretion (in the urine, great quantities of urea and small quantities of sodium chloride).

If quite different groups of diseases, comprising not only general affections such as burns, crushing, surgical shock, and general infections (e.g., Weil's disease) but also affections of special organs, such as liver diseases and myocardial infarctions, can cause either pure external azotaemia or extrarenal azotaemia plus renal failure—i.e., extrarenal uraemia—might not primary renal disease, too, occasionally be the cause of this symptom-complex? The following case may prove this assumption correct.

## Case 1

A man aged 48 underwent a calculus operation of the urinary bladder a few months before the onset of his present illness. Three days before his admission to hospital cystoscopic examination was carried out because of new troubles and was followed immediately by chills and high temperature. Death occurred 48 hours after admission. While in hospital he had two more chills and the usual symptoms of severe infection. X-ray examination revealed the presence of a calculus in the lower part of the right ureter. The urine contained only traces of albumin and leucocytes. A blood examination showed white cells 13,400 per cmm, with a marked shift to the left (juvenile cells 34%). Urea on the day of admission was 136 mg per 100 ml, two days later (the day of death) it was 153 mg. Uric acid was 8 and 9.7 mg per 100 ml respectively. The urine output for 24 hours amounted only to 1,200 ml. Its NaCl concentration was 0.8 g per litre and its urea concentration 18.4 g per litre, accordingly the total excretion on this day was NaCl 0.96 g, urea 22 g. The NaCl-urea ratio was 1:23. Though death resulted from severe septic infection the uraemia certainly was of clinical importance, the nature of the latter did not differ from typical extrarenal uraemia as seen in the course of various non-renal diseases which is proved by the dissociation of the urea-NaCl excretion and to some degree also by the fact that the urine was actually free from albumin and contained no casts and no cells except leucocytes.

Extrarenal azotaemia is probably also a manifestation of non-specific pathological processes caused by quite different diseases and appearing even in persons who never before have suffered from any kidney troubles. What will happen if a person suffering from chronic kidney trouble contracts one of the various diseases potentially

to cause extrarenal azotaemia or extrarenal uraemia? The occasional coincidence of chronic renal disease and extrarenal azotaemia or extrarenal uraemia seems natural if our basic conception is correct. May we expect interference from both these processes, and what will their clinical peculiarities be? Extrarenal uraemia appearing in a person suffering from chronic renal disease has already been reported (Zondek 1944). Two more cases each of a special type, may now be quoted.

### Case 2

A man aged 20 was found to be suffering from chronic nephritis two years before the present illness started. Since then he has had permanent albuminuria of 1-3 g per litre with leucocytes and casts. Four days before admission to hospital a fever started which lasted five weeks. The clinical picture resembled that of typhoid fever, all serological and bacteriological examinations however were negative. Amoebic hepatitis could not be entirely ruled out in view of the fact that temperature eventually subsided after treatment with emetine. Throughout the period of fever the quantity of albumin in the urine remained at about the same level as before, and there was no change after the patient's recovery, the same applies to cells and casts found in the urine. Blood pressure during the fever period and later, was not raised: systolic pressure was 100-110 mm Hg, diastolic pressure about 70 mm Hg. For the next 8-10 days after admission to hospital—the period with the highest temperature (102-103° F (38.9-39.4° C) in the morning and evening)—the findings in blood and urine were typical of extrarenal azotaemia, as seen in the following table.

Details of Case 2

Day of Illness	5	6	7	8	9	10	14	16	18
Blood Urea (mg per 100 ml)	60		50	36	23	24			36
Urea (g)	7.5			7.2		5.8			
NaCl (g per litre)	17	15	42	11	11	12	32	31	60
Urea excretion daily	0.5	1.6	36.0	3.4	2.5	12	18.4	12.8	10.6
NaCl (g)	0.85	0.8	2.1		0.6	0.72	1.92	3.4	
Urea (g)	20.7	22.5	18.0		1.4	18.7	11.0	13.0	

This case is one of extrarenal azotaemia caused by general infection in a person suffering from chronic nephritis. The extrarenal azotaemia and the chronic nephritis existed separately and did not interfere with each other. Following the accepted lines of diagnosis the rise of urea and uric acid in the blood would be considered to have been associated with the existing nephritis, and accordingly a state of true uraemia would be assumed. There is however no doubt that the condition in question is one of extrarenal azotaemia which may occur in patients suffering from a similar infection without the kidneys being seriously affected. The extrarenal azotaemia is proved by the strong dissociation of the sodium-chloride-urea excretion (NaCl-urea ratio up to 1:28) and a daily excretion of urea greatly exceeding that resulting from protein intake. The rise of urea and uric acid in the blood is probably due to increased endogenous breakdown of protein only, considering the high urea concentration in the urine (up to 41 g per litre) renal insufficiency can hardly be assumed, at least the insufficiency, if it existed, was much less pronounced than it might have been under similar conditions in persons not suffering from any chronic kidney troubles.

### Case 3

A woman aged 46 had had her right kidney removed 16 years ago on account of renal calculus. Since then there had been no more complaints concerning the kidneys. Some weeks before admission she had a gall-bladder attack with chills and pyrexia lasting a few days. Another and particularly severe attack started a week before admission, at the time of which she had very high temperatures of septic type, chills,

jaundice, and local peritoneal symptoms which lasted five days, from the sixth day all these symptoms subsided. Bile pigments including bilirubin which were present in abundance at the height of the illness likewise disappeared from the urine. At the time of the high temperature the urine contained albumin up to 1 g per litre, after that only traces were found. In addition there were always a moderate number of leucocytes but no other pathological elements. For sodium chloride and urea in blood and urine see the table. After an interval of three months

Details of Case 3

Day of Illness	8	9	11	12	14
Blood					
Bilirubin (mg per 100 ml)	12.0				2.0
Urea	110	96	60		32
Urine					
NaCl (g per litre)	2.6	1.6	1.4	2.0	2.4
Urea	7.0	7.6	12.0	18.0	24.0
Urinary excretion daily					
NaCl (g)	2.6	1.9	3.2	4.0	7.2
Urea (g)	7.0	9.0	29.0	36.0	72.0

during which the patient felt comparatively well, she had another gall-bladder attack with the same clinical symptoms as the previous one. The sodium chloride and urea findings in blood and urine were also similar.

Case 3 is one of severe acute cholecystitis complicated by a state of acute uraemia. The urinary excretion, at least in the first three days, of only small amounts of urea in spite of a high urea level in the blood suggests that the renal insufficiency must have been rather severe. But a process of extrarenal azotaemia, too, must be assumed. This, however, was not recognizable until, from the third day onwards, the daily urinary excretion of urea rose (to 37-70 g) while the urinary excretion of sodium chloride still remained low, the sodium-chloride-urea ratio was up to 1:10.

Extrarenal uraemia is a rather frequent occurrence in severe liver diseases complicated by jaundice (hepato-renal syndrome), therefore at first sight Case 3 does not seem to present any uncommon feature. But further examination revealed some findings deserving close consideration. X-ray examination of the kidneys showed that the pelvis of the left kidney (the right kidney had been removed) was almost entirely filled by calculus masses. A urea-clearance test carried out several weeks after the patient's complete recovery from the acute cholecystitis and the acute uraemia showed 22% of the normal value.

From these findings there can be no doubt that the patient must have been suffering from chronic renal disease with renal insufficiency for a long time, though the latter was not severe enough to raise the urea level of the blood so long as there was no special call upon the kidneys. But the condition changed definitely when, in consequence of the acute liver affection, a process of extrarenal azotaemia set in, thus forcing upon the kidneys the task of eliminating a much greater quantity of substances containing non-protein nitrogen. Yet there is an additional factor to be considered. Since in severe liver disease acute renal insufficiency associated with extrarenal azotaemia may occur even in persons who have never before suffered from any kidney disease the chances of its appearance may of course have been greatly enhanced because of the already impaired function of the kidneys. But, however severely the pre-existent chronic renal disease may have affected the course and the severity of the acute uraemic state, the latter must be considered to belong to the group of extrarenal azotaemia plus acute non-specific renal insufficiency—i.e., extrarenal uraemia.

### Discussion

Chronic and acute uraemia differ from each other not only in their clinical course but in the pathological

processes upon which they are based. Chronic uraemia may occur in the advanced or final stage of all chronic renal diseases. It is a remarkable fact that the morphological changes do not vary greatly according to the primary cause of the renal disease. Whichever the latter may be (chronic nephritis, malignant hypertension, pyelonephritis, or even renal diseases not belonging to the group of Bright's disease), the morphological process met with when chronic renal insufficiency makes its appearance is that of contracted kidneys. Nor can there be any doubt that renal insufficiency in these cases is closely related to the morphological process, and that chronic renal insufficiency has no other origin than the pre-existence of renal affection and its histological manifestations.

The genesis of acute uraemia, however, is of a different nature. In acute glomerulonephritis, for instance, it is the affection of the glomerular vessels, eventually leading to glomerular ischaemia, which must be held responsible for a possible occurrence of acute renal failure. But, whether the original nature of this affection be a functional spasm (Volhard, 1931) or a true endocapillaritis (for literature see Fishberg, 1939), the pathological process represents, as generally assumed, nothing but a special body-reaction ("allergic" according to Schick) to an extrarenal process—i.e., streptococcal infection in general. Glomerulonephritis, however, most certainly represents the background of only a minority of all cases of acute uraemia, while the majority belong to that group of renal failure defined here as extrarenal uraemia. Actually the theory that acute uraemia is due to glomerulonephritis and the latter to an extrarenal process is not quite correct, since the former is to some extent also extrarenal. In spite of this the terms should not be changed, at least not at present. Since acute glomerulonephritis and what it stands for represent a body-reaction to a rather specific cause—i.e., streptococcal infection—while extrarenal uraemia owes its occurrence to a variety of diseases, the big difference in the incidence of the two forms of acute uraemia cannot be surprising. How wide this variety of causative diseases is may be realized when it is said that even acute uraemia occurring in patients suffering from chronic renal diseases may be of the type of extrarenal uraemia. The occurrence of acute uraemia in cases of chronic renal disease has always been a difficult matter to explain, since the latter, according to its morphological characteristics, supposedly leads only to chronic uraemia. Perhaps the observations reported here may throw some light on this question.

In cases of extrarenal uraemia renal insufficiency may be regarded as functional. Though marked and well-defined morphological changes may be met with (Zondek, 1944, 1946), particularly of the tubular apparatus (degeneration or even necrosis of the epithelium, chiefly that of the ascending loop of Henle and of the distal convoluted tubules), they do not, even in the severest cases, represent a necessary finding, accordingly pathological elements such as albumin, cells, and casts in the urine may be absent. A striking difference must be assumed between the pathological processes underlying the uraemia in cases of acute glomerulonephritis and that in cases of extrarenal uraemia. While the former condition is characterized by an affection of the glomerular capillaries (functional spasm or endocapillaritis), sometimes verging on total glomerular ischaemia, in the latter a similar process has never been detected by microscopical examination. In addition, in cases of extrarenal uraemia blood pressure is found to be normal or even particularly low, while it is high in cases of uraemia connected with acute glomerulonephritis. This rise in blood pressure is only an expression of the vascular process mentioned above and is not restricted to the kidney

vessels alone. On the other hand, disturbances of the blood supply to the kidneys may also be responsible for the renal failure in cases of extrarenal uraemia (Fishberg, 1939, Maegraith *et al.*, 1945, Trueta *et al.*, 1946), they are, however, of a different nature from those typical of acute glomerulonephritis.

According to Fishberg, reduced renal blood flow is the decisive change found in "prerenal" uraemia, Maegraith *et al.* and Trueta *et al.* in addition to the reduction in the total blood flow, particularly stress a redistribution of the blood flow within the kidneys, which latter, in their opinion, is characterized by a whole or partial diversion from the cortex. According to Trueta *et al.* this change in blood supply is due to abnormal nervous reflexes—a suggestion advanced on the strength of very interesting and important experiments. The conception of a redistribution of blood flow within the kidneys fits in very well with the morphological renal findings as described by many authors (for literature see Maegraith *et al.*) and recently again confirmed by Darmady (1947)—namely, that in cases of extrarenal uraemia the cortex is always found to be pale and anaemic, while there is a marked congestion of the juxta-medullary area and an engorgement of the vessels in the medullary zone.

The fact that extrarenal uraemia is always associated with increased endogenous breakdown of protein led to the assumption that metabolites originating from this process may affect the kidneys and be responsible for the occurrence of renal failure (Zondek, 1944, 1946). This hypothesis does not contradict that of Maegraith *et al.* and Trueta *et al.*, who regard the disturbances of the blood supply as the decisive causative factor. Possibly the supposed metabolites—as also considered by the above mentioned authors themselves—may affect the nervous centres and thus become the cause of the abnormal blood circulation within the kidneys.

Obstruction of the urinary passages has until recently been regarded as the exclusive cause of acute uraemia, such as may occur after intravascular haemorrhages—e.g., blackwater fever, transfusion of incompatible blood, and other acute haemolytic processes—as well as that sometimes occurring in the course of treatment with sulphonamides. Precipitated pigment and precipitated crystals of sulphonamides were respectively supposed to obstruct mechanically the tubules (intrarenal obstruction) and the lower parts of the urinary passages—i.e., the pelves of the kidneys and the ureters (extrarenal obstruction). Such a mode of action may account, indeed, for certain cases of uraemia—i.e., those where great masses of crystals of sulphonamides obstruct the pelves and particularly the ureters. According to more recent investigations (Murphy and Wood, 1943; Foy *et al.*, 1943; Maegraith and Findlay, 1944), however, the possibility of intrarenal obstruction as the only or even the main cause of uraemia must be abandoned, and this holds true in cases of uraemia associated with haemolytic processes as well as those caused by sulphonamides, etc. The direct toxic action of drugs (sulphonamides, compounds of mercury) on the renal tissue may be considered possible. But this can hardly be the case in acute haemolysis. Since haemolytic processes always represent diseases of a serious character, it seems from the first more likely that renal failure in these cases is of the nature of extrarenal uraemia such as occurs in so many other diseases characterized by a turbulent course. Support for this assumption can be found in the fact that the morphological renal changes met with in cases of blackwater fever and transfusions of incompatible blood have been observed to resemble closely those which may be detected in cases of undoubted extrarenal uraemia such as crushing and pyloric stenosis (for literature see Maegraith *et al.*)

There may remain cases of acute uraemia which do not belong to any of the groups referred to, but they cannot be numerous. On the other hand we may assume that the great majority of all possible cases of acute uraemia have been met with and been grouped, and in the result extrarenal uraemia has been found to account for most of the cases in question.

There is general agreement that contracted kidney is the pattern for *chronic* uraemia. It may not be an exaggeration to assert that extrarenal uraemia is, to say the least, the most frequent pattern for *acute* uraemia. As to the pathological processes typical of extrarenal uraemia, the following triad of specific features—increased endogenous breakdown of protein, disturbance in the blood supply to the kidneys and certain morphological changes in those organs—has so far been recognized. They, all or in part, form the background for the renal failure, the nature of which, however, even if recognized as functional, is not as yet clearly defined. There is, for instance, no certainty whether the chief cause of the functional disturbance is glomerular filtration or tubular reabsorption or whether it comprises both of these basic processes, nor is it certain what the peculiarities of these processes are. These questions certainly open a wide field for investigation.

It cannot be denied that the term "extrarenal uraemia" (and also "prerenal uraemia") may give rise to some misunderstanding in so far as it may be considered to infer that there exists a state of uraemia where renal insufficiency does not represent the basic process. Such a conception, of course, does not fit in with the facts. In "extrarenal" uraemia renal insufficiency does not play a smaller part than in any other condition determined as "uraemia". The term "extrarenal" refers to the primary disease, which in extrarenal uraemia is not necessarily a renal affection as in the classic form of uraemia. The eventual misunderstanding will certainly be avoided by accepting the term "renal anoxia" as proposed by Macgrath *et al* (1945).

But, even admitting that the uraemia in question may actually be caused by renal anoxia only, the two processes can hardly be identified with each other. The fact that this uraemia is caused by renal anoxia certainly does not justify the conclusion that in turn renal anoxia necessarily leads to renal failure. For comparison, the subject of cardiac pathology may be referred to. Though acute cardiac failure can be caused by coronary failure, the latter does not necessarily involve the former, therefore the term "coronary failure" cannot replace that of "cardiac failure". For the same reason the term "renal anoxia" can hardly be applied when a state of renal failure is to be expressed.

In a previous publication "extrarenal uraemia" was designated also as "functional renal failure", but there may be arguments against this term also. First, in view of the morphological renal changes found in cases of extrarenal uraemia the functional nature of the latter might not be regarded as absolutely proved, secondly, other forms of uraemia, such as that which occurs in cases of glomerulonephritis, may be functional too. If "extrarenal uraemia" for the reason given above should no longer be regarded as wholly appropriate, the term "acute non-specific uraemia" might best fit in with all the facts.

#### Summary

- Acute uraemia occurring in cases of chronic renal disease may be of the type of extrarenal uraemia.
- Extrarenal uraemia represents the pattern for most of the cases of acute uraemia.
- The term "extrarenal uraemia" may be replaced by "acute specific uraemia".

## FIBROSITIS

BY

JAMES CYRIAX, M.D.

Physician to the Department of Physical Medicine,  
St Thomas's Hospital London

Fibrositis has been divided into primary and secondary. This is a separation with which I am in the fullest agreement, for in my opinion primary fibrositis is an imaginary disease and secondary fibrositis is a real entity.

#### Primary Fibrositis

Controversy has gone on for many years about the nature and identity of the different disorders included by common consent under this heading. The existence of fibrositis is affirmed by most clinicians, denied by most pathologists, but in the absence of an alternative explanation for the symptoms and signs purely negative views have carried little weight.

It is my purpose to draw attention to the ready solution to the problem of the existence or not of fibrositis that can be obtained by going back to first principles. This involves taking a detailed history, making a clinical examination of the patient, and drawing deductions on accepted lines from the physical signs discovered in each case. If this is done the conclusion is forced upon the unprejudiced observer that the symptoms so readily ascribed in the past to "rheumatic fibrositis" (i.e., fibrositis coming on for no apparent reason) are all in fact the result of articular lesions. I say "unprejudiced observer" advisedly, for I started my professional life as the very reverse, and it is only recently that I have been able to convince myself that the condition has no real existence.

#### Historical Note

In 1816 Balfour described fibrous thickenings occurring in the muscles in chronic rheumatism, Froberg, in Weimar, again drew attention to them in 1843. Sir William Gowers, in an article on lumbago in 1904, coined the term "fibrositis" to denote inflammatory changes in the fibrous structure of the sacrospinalis muscles. He went on to point out—perfectly correctly, as time has shown—that subsequent sciatica is "primarily an affection of the fibrous sheath of the nerve." Ever since, the disease has been recognized by medical men as a true entity. For example, Stockman (1920) shows photomicrographs of inflammatory changes detected in excised fibrous tissue from patients with fibrositis. Steinberg (1942) illustrates polymorphonuclear infiltration and proliferation of fibroblasts in a piece of the trapezius muscle excised from a woman who for 14 years had had generalized muscular stiffness ascribed by several

other physicians to a functional disorder. Another excellent photograph shows loss of cross-striation, disappearance of nuclei, and fibroblastic activity in a section of the latissimus dorsi muscle excised during the second week of recurrent lumbago.

Copeman and Ackerman (1944, 1947) carried this work a stage further; they searched for abnormalities of the trunk muscles in soldiers, whatever the cause of death. They began by postulating that fibrositic pain in the back was a well-known clinical entity and described lumbo-ilio-sacral trigger-points, myalgic spots, and tender rheumatic nodules as part of the disorder. Nothing suggesting inflammation of the soft tissues was found at post mortem, therefore pain experienced in this area was correlated with herniation of fat-lobules present in the muscles. These studies received widespread approval and were followed by a confirmatory paper by Hench (1946). He sought and excised such lumbar herniations, with complete relief from symptoms lasting 6 to 36 months in 34 out of 37 cases of back-ache. In a book completed in 1945 but not published till 1947, though I stigmatized diffuse fibrositis in the lumbar region as an imaginary disease I had not yet taken the logical step of discarding it as a possible cause of cervico-thoracic symptoms.

These authoritative opinions on a disorder whose existence has been widely affirmed for more than 40 years, backed by the demonstration of pathological changes in excised tissue, provide a formidable array of seemingly relevant fact. No one denies, of course, that these changes occur, it is their bearing on symptoms experienced in that region which is called into question in this paper. My views serve to illustrate the time-worn truth that anatomical diagnosis must precede pathological investigation. Until the tissue at fault has been singled out microscopy is out of place.

#### Preconceptions to be Discarded

1 *That Muscle Spasm Denotes a Disorder of Muscle*—Spasm of muscles about some point is a secondary phenomenon designed to protect a painful structure. Common events are prevention of a joint from being moved beyond a certain range (e.g., in arthritis) or about an inflamed viscus (e.g., in appendicitis). Generalized muscle spasm, apart from congenital myotonia, is also a secondary disorder caused by fear, cold, upper-motor-neurone lesions, tetany, toxins, etc. Temporary spasm of a single group of muscles can be brought about by unaccustomed exercise—e.g., in the adductor muscles of the thigh after riding. *Thus the existence of spasm of several muscles provides a strong indication that the muscles themselves are normal.* Its detection should lead to a search outside the muscles for the cause of the spasm.

2 *That Muscles in Spasm are Tender*—At the knee or ankle, for example, where muscles and joints do not overlap, it is obvious that the pain and tenderness lie at the joint, not in the muscles, however wasted they may be and however ready to spring into spasm to protect the joint.

3 *That Tenderness of Muscle Indicates a Muscle Lesion*—Many muscles are normally tender at only one point in their extent—e.g., the deltoid insertion at the humerus, the extensor bellies overlying the head of the radius. Moreover, in cases of root pressure in lumbar and cervical disk lesions genuine unilateral deep tenderness of muscle is often found. It was tempting to ascribe this phenomenon to small areas of fasciculation secondary to the lower-motor-neurone lesion, but it occurs in muscles situated where the pain is felt but not supplied by the damaged root—e.g., the trapezius and levator scapulae muscles in seventh cervical root pressure. The chief assistant in the department, Dr M. Woodhouse, has kindly carried out electromyograms on

the vertebro-scapular muscles in these cases and has established that fasciculation is absent there. Hence the hope once entertained that the cause of referred tenderness was to be found in a number of small areas of neurogenic spasm within a muscle has had to be abandoned. *It is never tenderness of a muscle, but pain elicited by the appropriate resisted movement that identifies a muscle lesion.*

4 *That Nodules or Crepitus at a Muscle are Significant*—When excised, the nodules so often felt at the lumbo-gluteal region are found to consist of collections of lobulated fat lying superficially to the muscles. Copeman and Ackerman have shown that lobules of fat occur also in the substance of the sacrospinalis muscles. Correct interpretation of the physical signs serves to demonstrate that they are not the cause of symptoms felt in the lumbo-gluteal region. It merely so happens that pain and tender fat deposits are both common there. Yet for generations deep massage to these innocent little swellings has been given under the best auspices. The same applies to muscular crepitus, to which I used to attach importance when the idea of nodules had to be abandoned. It was puzzling to find that stringiness and coarse grating in a muscle did not alter when a patient's symptoms ceased (Cyriax, 1941). The answer is obvious now: muscular crepitus is a perfectly normal phenomenon, felt most easily at the cervico-thoracic extent of the erector spinae muscle.

5 *That Limitation of Movement in More than One Direction can Result from a Muscle Lesion Alone*—Myotendinous lesions are usually associated with a full range of movement at the affected joint—e.g., tennis-elbow, supraspinatus tendinitis. A muscle lesion may, however, limit movement in one direction—e.g., adherence of the quadriceps muscle to the shaft of the femur limits the range of flexion at the knee-joint, dorsiflexion of the foot is limited for a few days after a minor rupture in the belly of the gastrocnemius muscle. Though the movement that stretches the damaged muscle may be limited, all the other movements of which the joint is capable remain of full range.

6 *That Examination of Conduction Along a Nerve Suffices*—When pressure is applied to a nerve, pain results at first from interference with its sheath. If this continues, signs of involvement of the parenchyma may in due course appear, but this is by no means certain (Cyriax, 1942). Hence, when pressure is exerted on a nerve by, for example, a prolapsed intervertebral disk or a cervical rib many cases will remain unrecognized if the examiner awaits the appearance of clear evidence of parenchymatous involvement. At present dural and nerve-sheath lesions unaccompanied by evidence of parenchymatous change are usually labelled fibrositis and provide a large number of diagnostic errors.

#### Clinical Examination

In suspected fibrositis, as in any other condition, the physical signs must be sought and properly interpreted. Deductions can also be drawn on the nature of the disorder from the signs that in due course appear in patients who get worse.

The following uncontroversial principles should be born in mind. (1) Passive movements indicate only the state of the joint. Limitation of movement in more than one direction indicates an articular disorder. (2) Resisted movements indicate only the state of the muscles. Pain felt when a muscle contracts, but no weakness, implies a minor myotendinous lesion, weakness without pain implies complete rupture or nervous disease. (3) A painful arc, or pain only on the relaxed side when a joint is moved passively, indicates that the lesion is pinched where it lies between bony surfaces.

### Fibrositis at the Neck and Trunk

Let us now consider the physical signs and the subsequent history in patients hitherto regarded as suffering from rheumatic fibrositis.

**Acute Rheumatic Torticollis**—The patient often wakes up and finds himself prevented by severe lower cervical pain, more marked on one side than the other, from moving his neck at all. Examination shows perhaps lateral deviation of the neck, limitation of movement in all directions at the cervical joints, more marked in some than in other directions and pronounced muscle spasm. These signs clearly indicate an articular lesion. In fact the condition is due to an attack of internal derangement—lumbago in the neck as it were—and the signs are of the same order. If spontaneous reduction does not soon occur the pain usually shifts to one side only of the base of the neck. The pain is now felt solely in the scapular area, yet what possible lesion of the muscles hereabouts (trapezius, levator scapulae, rhomboid, latissimus dorsi, spinatus, serratus anterior) could conceivably prevent nearly all active and passive movement at the neck while leaving the voluntary scapular and arm movements free and painless?

**Vertebro scapular Fibrositis**—The patient may start with bilateral pain that shifts to one scapular area or the symptoms may come on gradually and be unilateral from the first. Examination usually shows a full range of movement at the neck, the extremes of some movements hurting or others not. The resisted movements of the neck and scapula are painless. Can one imagine any unilateral lesion of the paravertebral neck muscles or of the vertebro scapular muscles, however nodular or crepitant they may appear to be (before during and after?), that leads to pain felt at the extremes of range at the cervical joints but to no discomfort when the resisted neck and scapular movements are tested? Spontaneous reduction may take place or the condition may become stationary. If the displacement increases the pain begins to radiate down the upper limb; tingling may be felt in the fingers.

**Brachial Neuritis**—In most cases the pain is severe worse at night and uninfluenced by use or rest of the painful limb. Examination shows that one or other of the neck movements increases the pain in the arm, another perhaps eases it. Limitation of movement in one or two directions may be noted. If as is usual, the sixth cervical joint is affected, weakness of the triceps muscle eventually becomes apparent in most cases, occasionally the power of flexion at the wrist is slightly reduced. Sluggishness of the triceps jerk is a rarity. A small patch of cutaneous analgesia may be detected at the dorsum of the index or long finger, often the patient complains of pins and needles and numbness with nothing objective to show for them. The analogy with sciatica has become complete and it is now generally agreed that brachial neuritis of the type described above is the result of a cervical disk lesion. Do not the precursors described under the two previous headings, form part of the same pathological process, but lesser in degree?

**Pleurodynia**—The pain is felt in the thorax posteriorly at first but usually spreading anteriorly if it becomes more severe. Sometimes the symptoms are purely abdominal or interior thoracic. It is difficult to prove that all these cases are caused by thoracic disk lesions, since the physical signs are in some cases equivocal. However examination may show that trunk side flexion towards the painful side causes pain. This indicates either that active contraction of the muscle hurts or that the lesion is squeezed. When, as is usual, resisted side flexion proves painless the muscle is excoriated. This means that the lesion lies intra-articularly and is pinched between two vertebral bodies. The same reasoning holds good when pain on active but not on resisted trunk extension is discovered. Cutaneous analgesia at an intercostal space is seldom discernible. Further proof that unilateral thoracic pain of the sort labelled fibrositis arises from a disk lesion may be obtained on attempted manipulative reduction, cases are met with in which this results in a click, whereupon suddenly the pain is wholly transferred to the other side of the chest. This must at least indicate that the lesion lies loose within a cavity situated at the middle of the body, and only one such exists—the intervertebral joint.

**Acute Lumbar Fibrositis (Lumbago)**—I regard lumbago as caused by internal derangement at a low lumbar intervertebral

joint (Cyrrix, 1945). The patient bends forwards and is suddenly immobilized in the flexed position by severe pain in the lower back, usually bilateral. Examination shows muscle spasm to limit lumbar movements. If this event was described as occurring at the knee joint, even if it was found that spasm of the hamstring muscles was limiting extension at the knee, no one would hesitate to ascribe the accident to internal derangement. Were lumbago really caused by acute fibrositis of the sacrospinalis muscles, with spasm, opisthotonos would result, in fact, the typical posture involves some degree of trunk flexion. Examination of a patient with acute lumbago shows marked limitation of movement in each direction at first, later the range of flexion and side flexion gradually returns, only trunk extension remaining impossible. Limitation in each direction indicates, as always in articular lesion, the sudden onset and the persistence of limitation of trunk extension only show that internal derangement took place. Posterior displacement of part of the cartilaginous disk provides a block at the back of the joint preventing full approximation of the posterior articular margins—i.e. trunk extension. Once a patient has had lumbago he is subject to recurrences as would be expected in loose body formation within a joint.

A few patients with lumbago display the lumbar signs of sciatica (lumbar deviation generally away from the painful side and limitation of trunk flexion) and a few patients with sciatica have the signs of lumbago but this is not surprising when one remembers that they are essentially the same disorder.

**Chronic Lumbar Fibrositis (Backache)**—The patient may feel his back give way or click during any heavy lifting and thereafter he finds himself subject to backache. Or he may develop pain more gradually for no obvious reason or even after a period of rest in bed. Recumbency in flexion is the common cause of the backache coming on during the puerperium. The pain is usually central becoming unilateral later. The reverse sequence also occurs.

In the early stage examination of the patient standing often reveals the existence of a painful arc especially on coming up from trunk flexion. This means that trunk flexion has allowed a slight degree of backward movement of the fragment of disk to take place while the joint types posteriorly. At the moment when the joint surface reverses their inclination a load is required the disk is sharply squeezed. Alternatively pain may be felt on the side towards which the trunk is bent associated with absence of pain when the same movement is tested against resistance. This phenomenon also implies that the lesion is so placed that it can be squeezed between the vertebral bodies. I used to think that painful pinching could occur between the lumbar transverse processes on side flexion of the trunk towards the painful side but this attractive idea has had to be abandoned. In other cases the signs are less distinctive but it is my experience that judged by the effect of manipulative reduction and of epidural local anaesthesia and by the later development of sciatica there is no difference between cases showing clear signs of a disk lesion from the first and those with equivocal signs.

**Gluteal and Sacrospinous Fibrositis**—The history may be of central lumbar pain perhaps recurrent which later settles in one buttock. Sometimes the pain starts in the buttock without any premonitory backache. Examination often shows that full trunk extension reproduces the pain in the buttock. Since the lumbar muscles and every structure at the sacrum or the buttock, apart from the joints themselves, are relaxed by this movement it follows that gluteal pain reproduced thus arises in the lumbar sacrospinous or hip joints not locally. If clinical examination then shows that the hip and sacrospinous joints are normal and that resisted contraction of each of the buttock muscles tested in turn is painless the lesion must lie at a lumbar joint. Epidural local anaesthesia quickly confirms the fact that the symptoms arise from pressure exerted at the side of the dura mater. Moreover most patients with this symptom are on the brink of sciatica hence the mere passage of time often makes the diagnosis obvious.

**Sciatica and Anterior Crural Neuritis**—When neurological signs are present it is generally agreed that disk protrusion is responsible. But it must be remembered that pressure exerted on a nerve root from without may not be sufficient in degree to affect conduction. Thus the tests for the sheath of the nerve

must also be given due weight. Hence the arrival at a diagnosis in cases of diffuse pain felt in the lower limb involves clinical examination of the lumbar spinal joints, the limb itself, the sheath of the nerve roots, and the parenchyma of the nerve roots. If patients with sciatica due to a disk lesion proved at laminectomy are questioned about the past they nearly all describe attacks of backache or lumbago preceding for many years the onset of sciatica. Has lumbar fibrositis then changed to a disk lesion or was it a disk lesion from the first?

#### Treatment of Primary Fibrositis

The underlying principle is simple—to secure reduction of the intra-articular displacement causing the symptoms. The actual techniques of reduction have already been described and illustrated (Cyriax, 1947).

**Neck**—This is usually easy, whether the patient has pain in the neck, the scapular area, or the upper limb—a few sessions of manipulation seldom fail to secure reduction. Occasionally continuous traction is indicated. Operation is required in 1% of all cases. Evidence of pressure on the spinal cord contraindicates manipulation.

**Thorax**—In simple cases one manipulation may result in full reduction, but eventual relapse is common. The difficult cases are very difficult, and it is easy to make the patient worse. If attempted manipulative reduction—even during traction—fails, rest in bed is indicated.

**Backache**—Recovery follows a few sessions of attempted manipulative reduction in about half of all cases. Rest in bed relieves some others but may lead to aggravation. Epidural local analgesia has a lasting effect on some of the remainder. Once well, the patient must be shown how to avoid further attacks of internal derangement (Cyriax, 1945). The passage of time, particularly in young patients, may bring relief if the protrusion erodes the body of the vertebra.

**Lumbago**—Two-thirds of all cases are considerably, one-third fully, relieved by one manipulation. Those whom manipulation does not affect should receive an epidural injection at once. Rest in bed ensures recovery in the end, but this consumes much more time and can often be avoided if these measures are tried first.

**Sciatica**—Manipulation is particularly apt to be effective in the elderly, in patients under the age of 50 it is likely to succeed in only one case in four. It is always worth trying, however, if the neurological signs are inconspicuous. Epidural local analgesia effects lasting improvement in others. Rest in bed eventually brings about spontaneous reduction in most cases. If sustained pressure results in atrophy of the affected nerve root the symptoms slowly disappear, though the signs of parenchymatous involvement increase. Operation is required in about one case in eight.

#### Secondary Fibrositis

There is no important controversy about the existence of four categories of this disorder—traumatic, rheumatoid, infectious, and parasitic.

**Traumatic Fibrositis**—This results from overuse or a single strain. Perhaps the best example is a tennis-elbow. A minor rupture occurs at the origin of the common extensor tendon from the lateral humeral epicondyle. Very little aching is set up at first, but, as the result of the torn edges beginning to join and then being pulled apart again each time the muscle is used, excess scar-tissue is laid down in the healing breach. Within one to three weeks the elbow has become quite painful from the development of chronic traumatic fibrositis at the site of the lesion.

Scarring in an intercostal or in the gastrocnemius muscle, golfer's elbow, teno-periosteal lesions at the wrist, crepitating teno-synovitis caused by overuse, abnormal scarring binding down a ligament after a sprain, capsular adhesions

at the shoulder after injury—all these and a number of other similar conditions can well be regarded as caused by post-traumatic fibrositis—more exactly, fibrosis. Ischaemic contracture, since the fibrosis affects the whole of the muscle equally, does not cause chronic pain. Treatment consists of deep massage, manipulation, or local analgesia, depending on the lesion present (Cyriax, 1947).

**Rheumatoid Fibrositis**—A number of observers (Curtis and Pollard, 1940, Freund *et al.*, 1942, 1946, Gibson, Kersley, and Desmarais, 1946) have obtained clear evidence from microscopy of tissues excised from patients with rheumatoid arthritis that nodular perineuritis and polymyositis complicate this disease. This is in full accord with clinical findings, which show that, in addition to the joint lesions, the tendon sheaths thicken, the tendons become rough and nodular (particularly in the palm), and bursae swell and fill with fluid. "The inference may be drawn that rheumatoid arthritis is a generalized affection of the fibrous tissues of the body in which the chief and most obvious incidence is on the capsule of the joints" (Cyriax, 1947).

**Infectious Fibrositis**—Epidemic myalgia (Bornholm disease) is an infectious disease the virus of which has been identified. It is characterized by fever, severe pain in the abdominal and thoracic muscles, and speedy recovery.

**Parasitic Fibrositis**—Infestation with *Trichina spiralis* sets up fever and painful swelling of the affected muscles, the skin over which may become red. The tendons may also be invaded. The disease comes on some ten days after eating infected pork. Active contraction of the affected muscle increases the pain. The symptoms and signs subside in the course of some weeks, after which the patient becomes completely unaware of the foreign bodies in his muscles.

#### Generalized Fibrositis

Rheumatoid arthritis is the only condition to which the term "generalized fibrositis" properly applies. By contrast, the disorder to which this name is often given is osteoarthritis of the spinal joints. This may lead to considerable aching over part or the whole of the trunk—areas where it so happens that muscular crepitus and fatty nodules are commonly detectable. Unrecognized osteitis deformans or spondylitis deformans is repeatedly called fibrositis.

Another disorder often called "generalized fibrositis" is psychoneurotic pain. The idea of generalized fibrositis has led to such concepts as "non-articular rheumatism" and "the psychological basis of rheumatism"—notions in which the cart is put before the horse. Clearly, functional pain is not rheumatism, and the discovery of the real cause should lead to revision of that ascription, not to an attempt to fuse two incompatible diagnoses.

#### Osteopathy

It is not infrequent that cases of pain felt at the trunk are mistakenly ascribed to various internal disorders but are in fact set up by root pressure from lumbo-thoracic-cervical disk lesions. Subsequent events in such cases, if the true diagnosis is missed, may appear to corroborate osteopaths' unfounded claim that their spinal treatments cure visceral disease. In a number of cases of obscure pain a disk lesion has proved responsible for the symptoms, and manipulative reduction has been successfully undertaken.

#### Summary

Primary fibrositis, both local and generalized is an imaged disease. The symptoms erroneously ascribed to this condition are all the result of articular disorders (largely internal derangement) at the spinal joints.

Secondary fibrositis (traumatic, rheumatoid, infectious, parasitic) is a real entity.

## Medical Memoranda

### Two Cases of Volvulus of the Caecum

In the *British Medical Journal* of Jan 18, 1947 (p 83) Mr Ralph H Gardiner reported three cases of volvulus of the caecum. He pointed out the embryological basis for the non-fixation of the caecum and right half of the colon which occurs in some cases as a failure of its embryological mesentery to disappear. This mesentery acts as a hub around which torsion occurs. He also pointed out that the onset of volvulus of the caecum may be sudden the patient suffering from violent abdominal pain, vomiting, constipation, and abdominal distension—signs of acute intestinal obstruction. On the other hand the onset may be slow and insidious with pain in the right iliac fossa, tenderness, and varying degrees of gaseous distension. The case may simulate an attack of appendicitis.

The following is a report of two cases with a mobile caecum and ascending colon due to the persistence of the embryological mesentery, around which torsion of the caecum had occurred.

#### CASE 1

On Oct 7, 1946 at 10 a.m., the patient, aged 60, was taken ill with a sudden attack of pain of a continuous nature, aching in character and "like frightful indigestion," and a feeling of fullness. She felt nauseous but was unable to be sick. The pain became so severe that she rolled in agony on the floor. She had trouble in passing flatus also, and she heard her "stomach roll." Next evening she kept complaining of great thirst, and had a whisky and soda which she returned. She was given morphine without effect and was then admitted to hospital. Her bowels had been opened the day before admission. An enema was without result and she did not pass any flatus.

Her past history showed that thirty years ago she had suffered from constipation and a persistent high temperature. She was seen by the late Lord Moynihan, who treated her with paraffin, 4 oz daily for six months. At the end of this time she underwent a laparotomy and "decayed intestine from birth" was excised.

On examination the patient appeared to be in great agony. She was very dehydrated, her tongue was dry and furred and the abdomen distended. Intravenous drip was set up and a right paramedian incision was made. Haemorrhagic free fluid was present in the abdomen, and an adhesion extended from the lateral wall over the ascending colon and caecum to the line of anastomosis of the old resection of ileum mentioned above. The caecum had twisted round the axis of the adhesion and the ascending colon. There was a hernia in the mesentery into which the small bowel had looped, causing further obstruction. The ascending colon was very much narrowed. The adhesion was divided, and the caecum, which was folded anti-clockwise, was unfolded clockwise, establishing free communication with the ascending colon. The proximal end of the adhesion (the adhesion adherent to the mesentery) was stitched to the region of the omentum, thus straightening the axis. No attempt was made to obliterate the hiatus.

The patient made an uneventful recovery and is to day feeling better than she has felt for the past thirty five years.

#### CASE 2

This patient was first admitted on July 16, 1941, when he was 6 years old. He had a sudden attack of colicky pain in the early morning, and more frequent and intense attacks after admission. His bowels had been opened the day before admission.

Examination revealed visible peristalsis, but nothing abnormal could be palpated abdominally. Examination per rectum was negative. Laparotomy disclosed volvulus of the caecum, which was mobile and grossly distended. Aspiration was performed, the volvulus was untwisted and appendicectomy carried out at the same time. The patient was subsequently discharged in a satisfactory condition.

On Oct 29, 1945, he was readmitted complaining of several attacks of abdominal pain and distension. An attack just prior to admission was very severe and he had had no motions or flatus for several days. A Ryle's tube was passed, with aspiration, and the patient was given a sippy enema followed by one of turpentine. He appeared to have settled down during his stay in hospital, and a radiograph on Nov 5 was reported on as follows: "Barium enema has revealed a rather unusual appearance in connexion with the large bowel, which appears to be displaced towards the left; there is no definite evidence of any obstructive lesion. Some irregularity in the region of the caecum suggests the possibility of adhesions, no definite evidence of any malignant infiltration has been discovered. The patient's general condition cleared up and he was discharged."

He was again readmitted on Feb 10, 1947 with a history of abdominal pain 'at the bottom of the stomach' that was colicky in nature. It had become continuous during the last hour but was not as severe as when of a colicky form. He had vomited five times since the onset of the pain. His bowels had been opened on the day before admission and on the day when admitted. There was no associated loss of weight. On examination the patient's tongue was clean. He pointed to the mid hypogastrium as the site of the pain. The abdomen moved on respiration and he complained of tenderness just lateral to the scar of the right lower paramedian incision. There was a tympanic note on percussion of the abdomen. Peristalsis was heard and the abdomen was soft with voluntary guarding. The patient moved about without undue stress or strain. Aspiration was carried out and clear fluid obtained. A flatus enema was given with a fair result.

Several symptoms which had cleared up during the first day or two in hospital recurred and when he began to vomit laparotomy was carried out under spinal analgesia. At operation the previous scar was excised. On opening the abdominal cavity the caecum was found to be lying across the lower abdomen and left iliac fossa. It had rotated once clockwise. On undoing the caecum a strong adhesion was found at its upper end and this made the ascending colon adherent to it. There was narrowing of the ascending colon at this point. The ileum was also adherent to the lower part of the caecum. Other adhesions were present these were separated. The caecum was replaced in the right iliac fossa and stitched to it lateral abdominal wall. An adhesion from the descending colon to the above mass of adhesions was also found. There was much gaseous distension in the caecum.

The patient made an uneventful recovery and remained well until July 31, 1947 when he was readmitted with bilateral broncho-pneumonia and abdominal distension from which he died.

#### COMMENT

As pointed out by Mr Gardiner volvulus of the caecum occurs more often than has been reported and should be kept in mind in arriving at a diagnosis in cases of intestinal obstruction. As can be seen from the two cases the cause of the volvulus was failure of the caecum and ascending colon to become attached to the posterior abdominal wall—in other words, caeco-colic mesentery. The onset of symptoms as previously mentioned were those of acute obstruction—namely sudden onset, violent abdominal pain, vomiting, and constipation. The onset can also be chronic intestinal obstruction as mentioned in the review of the history of the second case.

I wish to thank Mr W M Morrison and Mr J G I Ford, honorary surgeons for permission to publish these cases and Mr Morrison also for guidance.

I R SHULMAN B.M. B.Ch.  
Late Resident Surgical Officer, Dury Infirmary

New regulations entitled the Clay Works (Welfare) Special Regulations 1946 (No. 1547) which come into operation on Oct 1 supersede the Clay Works (Welfare) Order 1932. The regulations extend the provisions of the order with regard to washing facilities, clothing accommodation, and welfare in factories in which clay, shale, sand, lime, or similar materials are made into bricks, tiles, blocks, slabs, pipes, stiles and spurs, nozzles, or similar articles. They also specify that an ambulance room should be equipped with a glazed sink with hot and cold water always available while people are at work, a table with a smooth top, means of sterilizing instruments, a supply of suitable dressings, 1 cot, a stretcher and a foot bath.

## Reviews

### DIABETES MELLITUS

*Diabetes Mellitus in General Practice* By Arthur R. Colwell, M.D. (Pp 350, illustrated \$5.25 or 39s) Chicago Year Book Publishers Inc. London H. K. Lewis and Co.

The title of this book suggests a rather simple practical account, but in fact it is full of information of interest to the specialist. The chapter on diagnosis is good, and the author recognizes the existence of renal glycosuria. He believes that the diabetic condition should be as well controlled as possible in order to prevent the disease from becoming worse, and he makes a good case for this ideal, though he admits that it cannot always be achieved. He agrees that some patients feel better when not strictly "sugar free" and that they should be permitted to show some glycosuria, but he does not mention that many of these patients have a low threshold for sugar, continuing to pass it even though the blood sugar under the influence of insulin has decreased to less than 130-80 mg per 100 ml or less and naturally feel better when the blood sugar is between 80 and 180 mg per 100 ml. The rules for arranging the diet seem rather formidable, since they involve a calculation based on the weight, age, and activities of the patient and the estimation of the real glucose value of the diet and the amount of fat, so as to maintain the Woodyat formula. The arrangements for the exchanges of one kind of carbohydrate for any other of equal content also seem clumsy. The use of the 5-g values originally introduced by Leyton has never been adopted in the U.S.A., although it makes the variation of the diet so much simpler.

The chapter on insulin and its modifications is of great interest. The original amorphous insulin, which unfortunately is called by many names—standard, regular, ordinary, or soluble insulin—seems to be rarely used. Most often prescribed is the slow-acting, milky, protamine zinc insulin, though the slow-acting soluble globin insulin is also used. The account of the action of mixtures of equal quantities of ordinary and protamine zinc insulin is very good. The author does not think that a mixture of equal quantities of ordinary and protamine zinc insulin differs in its action from protamine insulin alone, since the amount of free protamine is too great. However, mixtures of two parts of ordinary to one of protamine zinc insulin, or of three ordinary to one of protamine zinc, are of use, especially for patients difficult to control by one dose of protamine zinc. He agrees with Woodyat that about 10% of diabetics are "labile" or difficult to control because they behave differently from day to day although the conditions of diet, food, and exercise are not altered. These patients are best given four doses of ordinary insulin a day, but by administering protamine zinc or globin insulin instead of ordinary insulin before the evening meal the number can be reduced to three. He does not refer to Hagedorn's protamine insulin without zinc, which is of real value in this type of case. The account of insulin reactions is good, and he mentions the failure of patients to recognize hypoglycaemia. This is one of the most serious problems at the present time, but the author has no suggestions for making these patients reliable again. His account of the treatment of acute infection and diabetic coma and other complications is well done. It is surprising that he does not discuss the oscillogram, which is so useful in determining whether a local amputation of a toe can be done or whether the operation must be above the knee. The book is well written but the arrangement of the diets makes it less useful to practitioners in Britain than it would otherwise be.

GEORGE GRAHAM

### LOCAL GOVERNMENT

*Local Government* By Sir A. S. MacNalty K.C.B. (Pp 218 4s 6d) London Methuen and Co., Ltd. 1948

In this addition to the series of Home Study Books the author has been set a task that he must have found almost overwhelming. Local government throughout our long history has been so chequered the growth of its functions so irregular and latterly so accelerated, and its present scope so diversified and

so unstable that the moving picture is hard to present in the form of a short documentary. Sir Arthur MacNalty has been remarkably successful in writing of a subject that is apt to be dry in language which makes pleasant reading. In four main parts he discusses the development and organization of local government, public health, various local authority services, and the future of local government. Within the available space he considers each aspect as fully as possible without lapsing into legal or official jargon. He does not hesitate to point out the dangers of control of local affairs from Whitehall, or the effect on the public health services of local lay bodies appointing medical officers of health, who run a risk of becoming local bureaucrats out of sympathy with their medical colleagues, but who usually avoid it. His sketch of the medical organization of central government departments might well have been expanded so as to bring out the fact that the grand fusion of 1919 seems to have done little to prevent the growth of the existing medical services, and the creation of new ones in other departments than the Ministry of Health.

The vast changes in local government administration, affecting both the social and the public utility services brought about by post-war legislation must have placed Sir Arthur MacNalty in difficulties. In the final part of the book he discusses briefly these changes, which are already putting out of date much that is written in the present tense in the earlier parts. He might have said more of the new revolution which is placing in the hands of nominated boards functions hitherto regarded as the normal responsibility of local elected bodies, a movement whose relation to the operations of the Local Government Commission is difficult to foresee. On the factual side there is little to criticize, but it is surely a surprising lapse on the part of a former Chief Medical Officer of the Ministry of Health to describe the agreed Askwith scales of salaries for medical officers in local government as "the B.M.A. Scale." This little book, low priced as it is, is recommended to all students of public health and social science.

RALPH M. F. PICKEN

### STANDARD METHODS IN BACTERIOLOGY

*Standard Methods of the Division of Laboratories and Research of the New York State Department of Health* Third edition. By Augustus B. Wadsworth M.D. Foreword by Gilbert Daildorf, M.D. (Pp 990, 109 illustrations 55s) London Baillière, Tindall and Cox 1947

Many bacteriologists must have considered writing a book on technical methods and shrunk from the prospect. The difficulties are enormous and success is almost impossible to achieve. Either the description must be so detailed as to be unreadable or small but none the less important points of procedure must be omitted. It is about as impracticable to master bacteriological technique by reading a textbook as it is to learn to drive a car by sitting in an armchair with an instruction manual before one. Scientific technique like the art of craftsmanship, can be learnt only at the bench: there is a personal element in it that requires actual demonstration. Moreover, there is not one technique but often several, and only experience can teach the individual worker which is the best for his particular purpose. This does not mean that books on technical methods are useless, but it does mean that they are generally unreadable. As works of reference they are often of undoubted value, particularly in their description of simple analytical tests, the preparation of reagents, the formulae of stains and nutrient media, and the codification of general rules for conduct in the laboratory and the animal house. It is in the dynamics of manipulative technique that they break down, and this part is best avoided.

The third edition of this well-known book inevitably evokes mixed feelings. Reaching now to almost a thousand pages it is an attempt to cover the whole range of bacteriology and immunology, with sections on clinical pathology, mycology, protozoology, and helminthology. The different portions vary in thoroughness of exposition. For example, the description of serological tests for syphilis, gonorrhoea, and tuberculosis occupies about 100 pages; on the other hand, the methods for studying individual organisms are discussed very briefly, no mention appears to be made of the coagulase test for staphylococci or of the absorption technique for the P.

test and the author disposes of the slide agglutination method of typing haemolytic streptococci in two short paragraphs. There are useful chapters on the composition of stains and reagents, on the formulae of nutrient media and on the large-scale preparation and standardization of vaccines and sera. There is a new chapter on the methods of biological assay and an account of an improved method of preparing cardiolipin. The book is well illustrated and there are useful appendices on the mode of collection of specimens, application forms and outfits. The laboratory worker will often refer to it, and Dr Wadsworth, who has been so largely responsible for building up the complex organization of the New York State Laboratories may justifiably take pride in the incorporation of his ideas in this recent edition to mark the occasion of his retirement from the post he has held so long.

G S WILSON

## PARENTS AND CHILDREN

*Parents Questions* Revised edition By the Staff of the Child Study Association of America (Pp 286 10s 6d) London Gollancz, Ltd 1947

This book is to be welcomed. It can be given to parents and it will not worry them or tie them up in knots over psychological theory. It will be kept lying around or at the bedside being picked up at odd times, being read at random. Gradually the answers given in 230 questions will be getting known. There is no doubt that the questions are exactly the ones that parents in Britain ask. 'Should you punish a child when he admits he has disobeyed you and says he is sorry?' 'We are getting a divorce. I don't know how to explain it to our son.' 'My fifteen-year-old daughter dresses in the most outlandish way. Is there anything we mothers can do?' 'My boy and girl quarrel constantly. Do you think I ought to interfere or let them fight it out?' 'Can we prevent our children from using slang?' 'My six-months-old baby wakes up and cries at night for no apparent reason. How can I train her to have good sleeping nights?' These are random samples.

Each answer takes up a page or two and the writers show tact and judgment and deep knowledge, and at the same time they avoid making the parent feel frightened or ashamed. They really do give advice and parents welcome this if it is done with due recognition of the difficulties inherent in any situation where things have gone wrong. An analyst could say that here is the right complement to the analytic treatment of individual children. As the great majority of children who are emotionally disturbed have no access to psycho-analysis it is fortunate that the authors make but sparing reference to the value that might come from such treatment if it were available. This is a revised version of a book first published in 1936 and would seem to justify its publication in Britain by being written in the kind of English we understand and by being concerned with the problems that beset us here, and perhaps others the world over.

D W WINNICOTT

Prof Boyd modestly claims that 'some of the more glaring errors have been corrected' in the fifth edition of his *Textbook of Pathology, an Introduction to Medicine* (Henry Kimpton, 48s), and new material on many subjects has been introduced. These additions consist chiefly of short paragraphs on subjects of minor importance. The popularity of the book is due to excellent illustrations and easy readability, its almost conversational and sometimes dramatic style sustaining the reader's attention. It gives the impression of having been dictated rather than carefully written. The outlook is at times superficial; for example, the pneumococcus is stated to have a marked ability to excite the formation of fibrin without any explanation of how the effect is produced. Has it really been proved that 'a pathologist or surgeon returning in robust health from a holiday is in greater danger from streptococcal infection than one who has finished a long winter's work involving constant exposure'? This paradox is typical of statements from which the book derives much of its interest, and sometimes this quality seems to have been attained at some sacrifice in other directions. There is also a lack of considered judgment on difficult or controversial subjects: the author briefly describes Menkin's work on inflammation, for instance, with no hint of whether he accepts its conclusions. On the other hand no book contains a better account of what pathology is or presents the subject in a more suitable way to the student of medicine. The patient as a whole is never lost sight of in the descriptions of what is happening in one of his organs.

## BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*My Life in General Practice* By H W Pooler M B (Pp 104 15s) London Johnson 1948

The varied life of a general practitioner over the last 50 years

*Principles of Occupational Therapy* Edited by Helen S Willard, B A, O T R, and Clare S Spackman B S, M S in Ed, O T R (Pp 416 25s) London Lippincott 1948

A general account by various authorities with references

*An Index of Treatment* Edited by Sir Robert Hutchison Bt, M D, LL D, F R C P, and Reginald Hilton, M A, M D F R C P 13th ed (Pp 972 84s) Bristol Wright 1948

A guide to treatment for the practitioner

*Psychiatry for the Pediatrician* By Halc F Shirley M D (Pp 435 25s) London Geoffrey Cumberlege 1948

An account of the psychology of children, illustrated by case histories

*Laboratory Manual on Fundamental Principles of Bacteriology* By A J Salle, B S, M S, Ph D 3rd ed (Pp 176 13s 6d) London McGraw-Hill 1948

Intended for students of bacteriology

*Heredity* By A Franklin Shull 4th ed (Pp 311 24s) London McGraw-Hill 1948

An outline of genetics

*A Practical Manual of Diseases of the Chest* By Maurice Davidson, M A, M D, F R C P 3rd ed (Pp 670 50s) London Geoffrey Cumberlege 1948

Intended primarily for the specialist in chest diseases much new material has been added

*Renewal Pages for the Nelson Loose-Leaf Surgery*, Vols IV and V *Surgery of the Thorax* and *The Technique of Trans-thoracic Resection of the Stomach and Esophagus* New York Nelson 1948

*Lectures to Nurses* By M S Riddell, A R R C, S R N 9th ed (Pp 460 16s) London Faber 1947

Lectures on practical work for probationer nurses

*Aids to Pathology* By J O Oliver, M B, B S, M R C S, L R C P 9th ed (Pp 332 7s 6d) London Bailliere Tindall and Cox 1948

The new author of this book has made many alterations

*Fundamental Principles of Bacteriology* By A J Salle, B S, M S, Ph D 3rd ed (Pp 730 36s) London McGraw-Hill 1948

A textbook with details of laboratory technique for the student

*The Future of Private Practice* By E Samson, F D S R C S, L D S, F C S (Pp 69 3s) London Cottrell 1948

A pamphlet on how far private dental practice may hope to survive after the introduction of the State service

*Critique of Homoeopathy* By O Leiser, M D, Ph D (Pp 121 6s) London Hippocrates 1948

A polemical defence of homoeopathy

*Handbook of First Aid and Bandaging* By A D Bellios, M B, B S, D P H, and others 3rd ed (Pp 512 5s) London Bailliere Tindall and Cox 1948

A textbook for the layman

*Laboratory Guide in Animal Biology* By R H Wolcott and E F Powell 2nd ed (Pp 113 9s) London McGraw-Hill 1948

A manual for the student of zoology

*The Care of Tuberculosis in the Home* By J Maxwell, M D F R C P 2nd ed (Pp 112 7s 6d) London Hodder and Stoughton 1947

Includes discussion of diet, collapse therapy, and tuberculosis in childhood

## BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JULY 31 1948

## SURGICAL TREATMENT OF HYPERTENSION

Surgical treatment aimed at reducing the blood pressure in cases of hypertension has now been on trial for ten years. In the opening pages of this issue of the *Journal* there is an important review of the subject by Dr R H Smithwick, who has been one of the pioneers in establishing the operative treatment of hypertension on a rational basis. He now reports on the progress of 256 patients followed up for from 5 to 9½ years after operation, the results being analysed according to examination of the eye-grounds, electrocardiograms, renal function, cerebral complications, and blood pressure. Other reports have come recently from Hinton and Lord,<sup>1</sup> and from Fishberg,<sup>2</sup> and a fair judgment can now be given on the value of surgery in this condition.

Is operation worth while? It is now generally agreed that, provided a proper selection of cases is made, operative treatment has a good deal to offer and its advantages outweigh its drawbacks. Those who may have limited experience in selecting patients suitable for surgery will find the recent reviews helpful. Hinton and Lord, for example, have studied 350 cases and have decided on criteria which would have eliminated as unsuitable all but eight of the thirty-eight patients who died shortly after operation. Fishberg stresses the importance of avoiding surgery in cases with arteriosclerosis and states that for this reason operation should seldom be performed on patients over the age of 50. Only 4% of the hypertensives he sees are considered suitable. Smithwick,<sup>3</sup> too, has given useful guidance by describing the types of case in which the results have been unsuccessful. While operation is in no sense curative there is now good evidence that in a fair proportion of cases it delays the progress of deterioration in the cardiovascular system and so prolongs life. Smithwick's comparison of his late results with those of non-surgical treatment supports this view, and Peet<sup>4</sup> and Fishberg found that patients with signs of neuroretinopathy have a better chance of survival with operation than without. Distressing symptoms such as headache, pounding in the head, restlessness, inability to concentrate, and vertigo are relieved or abolished by operation in a high proportion of cases. Many patients who have been unable

to work because of these symptoms have returned to full work, in some cases for years. A prolonged lowering of the blood pressure does not always accompany such relief, and Fishberg has good grounds for his view that the symptomatic improvement is due to a reduction in capillary pressure in the cerebral circulation which follows an increase in sympathetic tone in the upper part of the body after operation together with loss of tone in the lower part. In his follow-up study Smithwick has found that in most cases the blood pressure rises with the passage of years, and marked reduction for 5-9 years is seen in only 20% of cases. This is confirmed by Poppen and Lemmon<sup>5</sup> and by Palmer,<sup>6</sup> who states, however, that the results remain better than those achieved by medical means. The explanation of this rise in tension is not certain, but probably the original causes of the hypertension persist, and regeneration of the sympathetic fibres, which is always apt to occur, may well play a part. Notwithstanding this tendency, Smithwick's tables show that nearly 50% of patients have some sustained lowering of the blood pressure. The value of this can be judged from his finding that post-operative improvement in cardiovascular status is most marked in those cases in which there is a pronounced and sustained lowering of pressure.

Though operation offers these undoubted benefits there are some unwelcome effects. Apart from the operative mortality, now reduced in skilled hands and with careful selection of cases to 1 or 2%, post-operative pain is commonly severe and may continue for two months or more. In most cases a convalescence of several months is required, and it may be more than a year before a patient feels perfectly well. Giddiness or a transient black-out when getting up quickly is not uncommon and may persist for several months, and requires the use of elastic stockings and a lower abdominal girdle. Increased vasomotor tone in the upper part of the body may cause troublesome attacks of Raynaud's phenomenon in the hands. In males the inclusion of the second lumbar ganglia in the resections can cause loss of power of ejaculation and consequent sterility, but according to Poppen and Lemmon this by no means occurs in all cases. Patients with arteriosclerosis sometimes develop angina pectoris or severe mental depression and lethargy after operation, and therefore a history of typical anginal attacks and signs of cerebral arteriosclerosis are contraindications to operation. These drawbacks must be borne in mind when considering operation in any particular case.

There is still no general agreement on what should be the extent of the sympathectomy. Peet adheres to the limited supradiaphragmatic resection of the lower thoracic chain and splanchnic nerves. Smithwick extends this to include the first lumbar ganglion and is doubtful if wider resections are desirable except in cases with angina pectoris or tachycardia, in these he resects the thoracic chain up to the stellate ganglion. Poppen and Lemmon and Linton and his colleagues<sup>7</sup> extend the resection into the upper thorax, and Grimson<sup>8</sup> advocates total sympathectomy including the stellate ganglion. Fishberg's conclusion that cerebral symptoms are improved by reduction in the cerebral capillary pressure suggests that it is better to leave the stellate ganglion intact and so maintain cerebral

<sup>1</sup> *Ann Surg* 1948 127 681<sup>2</sup> *J Amer med Ass* 1948 137 670<sup>3</sup> *Amer J Med*, 1948 4 744<sup>4</sup> *J Amer med Ass* 1946 130 467<sup>5</sup> *Ibid*, 1947 134 1<sup>6</sup> *Ibid*, 1947 134 9<sup>7</sup> Linton R R, Moore F D, Simeone F A, Welch C E and White J C,*Surg Clin N Amer* 1947 27 1178<sup>8</sup> *Ann Surg*, 1941 114 753<sup>9</sup> *Edinb med J* 1947 54 545<sup>10</sup> *Studies of the Renal Circulation* 1947 Blackwell Oxford<sup>11</sup> *British Medical Journal* 1948 1 435

vasoconstriction Mitchell's<sup>9</sup> anatomical findings indicated that for complete denervation of the splanchnic area the resection of the chain should extend from the fourth thoracic to the third lumbar ganglia, and in this country there is a tendency to practise these more extensive resections. The effect of operation is to produce an immediate vasodilatation in the splanchnic area, and in the lower limbs when the resection extends below the second lumbar ganglia, with increase in sympathetic tone in the upper part of the body. The beneficial effect of the vasodilatation is due partly to a reduction in the peripheral resistance which leads to a lowering of the blood pressure, and partly, in all probability, to a lessening of the cortical ischaemia in the kidneys which results from vasospasm and the short-circuiting of blood through the juxta-medullary glomeruli, a mechanism revealed by Trueta and his colleagues.<sup>10</sup> Bourne<sup>11</sup> considers that the results of operation depend chiefly on whether the renal cortical insufficiency is mainly due to vasospasm or to organic changes in the glomeruli. The blood pressure rises rapidly within a few weeks of operation, probably because of the development of autonomous tone in the muscle of the denervated vessels—a finding well known after limb sympathectomy. The subsequent gradual rise, observed in some cases years after operation, is attributed by Poppen and Lemmon to regeneration of sympathetic nerves. Sweating tests have shown that such regeneration occurs, and Linton has reported the finding at secondary operation of a regenerated splanchnic nerve which had reconnected with the coeliac ganglion though it had been divided above the diaphragm. This tendency to regeneration is a further argument for the more extensive resections. However, physiological vasopressor responses such as the Valsalva manoeuvre remain absent or greatly diminished after operation, so that the vascular tree is protected from the high peaks to which the blood pressure can climb in most unoperated cases of hypertension. The alternative explanation given by Bourne of the gradual rise in blood pressure after operation is that permanent renal damage results in the further production of pressor substances which maintain a vicious circle of cortical ischaemia.

On balance there is no doubt that this great physiological experiment of extensive sympathetic resection should be continued in larger series of cases followed up for longer periods. It seems certain that a proportion of hypertensives, carefully selected and rather small, will continue to obtain great symptomatic relief and an improved life-expectancy.

### ATOMIC ENERGY RESEARCH

The Ministry of Supply has acted wisely in admitting correspondents of the scientific and lay press to its Atomic Energy Research Establishment at Harwell. The occasion was by no means the first on which representatives of the outside world have been given entry. A conference on nuclear physics, attended by some sixty visitors, was held there in the autumn of last year, and of the weekly discussions held at the establishment, to which the Director, Sir John Cockcroft, evidently attaches importance, about half are on non-secret subjects, and outside scientists take

part. Such contacts are clearly of value as much to the research establishment as to the visitors, but they can be no substitute for the wider information which has now been afforded. In his address of welcome Sir John made it clear that no atomic secrets were about to be disclosed, and that disclaimer is borne out by the account which we publish elsewhere in this issue (p. 263) of the work of the establishment so far as it concerns medicine and biology. But the extent to which demonstrations could be given, plant and equipment inspected, and information imparted on those strictly correct terms carries its own proof that the trouble taken by Sir John and his colleagues was worth while.

Many of the immediate benefits to be expected directly concern medical men. Like any other discovery which man may make, from the invention of steel to the separation of vegetable poisons, the results of atomic research can be used for his benefit or his injury. It is its misfortune that having been born in war the first application of atomic energy should have obscured the good which it has to offer. The power which can explode a bomb can also drive factory machinery, but there is much technological work to be done before the economic output of power for peacetime uses can appear as a practical development of atomic research. Ten years, in which much else can and may happen, seems a reasonable estimate for the realization of that hope. On the other hand the doctor, and no less the chemist, can easily understand the extent of the contribution which radio-isotopes produced in nuclear piles can make to knowledge. They have already assisted physiological and biochemical research in many directions, for the radioactive tracer method has been applied with success to such problems as the life of a red blood cell, the biochemistry of the developing embryo, the mode of action of penicillin on bacteria, and the mechanism of photosynthesis. One of the surprising facts revealed is that carbon dioxide, which has been regarded solely as a waste product in animal metabolism, can under exceptional conditions be "fixed" by man as well as by plants. The possibilities are evident, even if much of the work which has so far been carried out has been exploratory.

There has been some concern lest radioactive tracers might be used for repeated investigations in human subjects beyond the limits of safety which have been set for the workers at the Research Establishment. It is fortunate that it was soon recognized that the employment of minimal quantities is as desirable for accuracy of results in biological tracer experiments as it is for the safety of the individual. In the particular case of radiocarbon, which in some respects offers the greatest promise, there is the further complication that, whereas the active material is prepared in the first instance in the form of carbonate, most of its more interesting uses demand that the activity should be transferred chemically to some organic form. To overcome this difficulty the Medical Research Council has supported research on certain of the more important roads to synthesis, and the Department of Scientific and Industrial Research has arranged for a programme of microchemical organic synthesis to be undertaken by the Chemical Research Laboratory in order that the most difficult requirements may be met centrally.

It is expected, however, that laboratories capable of carrying out useful work with organic tracer materials will also be capable of undertaking whatever preliminary preparation of the material may be desirable. It will be some months yet before the full effects of the bringing into operation of the second Harwell pile are evident. In the interval the less powerful "gleep" has performed a useful service in familiarizing an increasing number of workers with the technical problems which arise when employing radioactive isotopes. It is not too much to hope that the larger supplies soon to be available will bring their own demonstration that there is much to be written on the credit side of atomic energy research.

### THE SPHENOID SINUS

The anatomy and comparative anatomy of the accessory sinuses of the nose have been well demonstrated for very much longer than their physiology has been understood. The latter has only come to the fore in relatively recent times, but there is already a much better understanding of sinus reactions and affections, and this has led to improvement in the treatment of these conditions. In this connexion tribute must be paid to the pioneer work of Jonathan Wright and H. Smith<sup>1</sup> and to Dr Arthur W. Proetz,<sup>2</sup> who has devoted so much time to this work. Appreciation of the importance of the ciliated epithelium, of its action against gravity and around corners, of its survival and continued function in quite advanced pathological conditions, and of the effect on its viability and activity of various drugs and chemicals, have put treatment on a rational basis. It is now recognized that even advanced pathological changes can be reversed, and this, together with the advent of chemotherapy and the antibiotics, has led to increasing conservatism in the surgery of the nasal sinuses.

At the recent Annual Meeting of the British Medical Association in Cambridge the Section of Otorhinolaryngology discussed the sphenoid sinus, and the opening paper read by Dr Proetz is printed elsewhere in this issue (p. 243). It was generally agreed by the speakers that "the acute sphenoid" was rarely encountered, and that differing as it does from other sinuses, such as the maxillary, in the thickness, blood supply, and glandular structure of its lining, the sphenoid sinus is not often the site of mucus stasis or polypoid change. Of all the accessory sinuses it is easily the best protected from changes of temperature, injury, and direct infection, and it is moreover well situated for the application of decongestive substances. These should be of low concentration and administered in a physiological medium. 0.25% of ephedrine sulphate in normal saline is more effective than a strong solution. Adrenaline is better reserved for haemostasis, and cocaine is poison to the cilia and should only be used for analgesia. Only solutions are usually inimical to ciliary activity.

Surgery, when required, need not be radical, and oblitative measures should not be attempted. If ciliary activity is preserved, drainage does not have to be "dependent", in fact, it is impossible to provide for dependent drainage in both erect and recumbent positions. Considering the inaccessibility and the importance of the anatomical structures surrounding the sphenoid—Proetz lists 13—it is fortunate that the weight of experience is in favour of conservative treatment.

### THE LUNGS IN DIPHTHERIA

The cardiac and nervous sequelae of diphtheria are usually regarded more seriously than the pulmonary complications. A bronchopneumonia may of course occur in severe cases of laryngo-tracheal diphtheria either by extension or by superimposed secondary infection. Then again bronchopneumonia after tracheotomy used to be a more serious hazard, before chemotherapy reduced the risk. The development of pneumonia in the high proportion of over 10% of 753 cases of diphtheria was reported by Togasaki<sup>1</sup> and his colleagues, one-quarter of these patients died, but the more recent use of sulphonamides has since improved the outlook. Most workers in fever hospitals now use penicillin in the treatment of laryngeal diphtheria as a routine, and with sulphadiazine as a stand-by death from bronchopneumonia is much less common than it was. The only other pulmonary complication which might be looked for at necropsy is the extensive subpleural and interstitial haemorrhage which can occur as part of the general haemorrhagic tendency in severe hypertoxic cases. It is probably true to say that the occasional patient who developed a terminal pulmonary oedema caused little comment, since existing paralyses and cardiac embarrassment probably provided adequate explanation of the condition. The interesting suggestion has now been made by Janbon and Chaptal<sup>2</sup> that toxin may be directly responsible for the pulmonary oedema in such cases.

In their series of cases the first seven patients developed a transient pleurisy, almost always accompanied by frank effusion. In most of these it was difficult to exclude a co-existent cardiac or renal complication as the cause, and though in one patient the pleurisy appeared in the stage between the end of the early toxic effects on the heart and the later neuropathies it would be unwise to overlook the possibility of a relationship. The division of any acute infection into stages is a valuable convenience for the purposes of clinical description, but it should not obscure the fact that illness must be viewed as a whole, each change being dependent on what has happened before. In a further four patients (three of whom died) acute pulmonary oedema developed. The authors discuss at some length the possibility that the oedema may result from toxic damage to the vagus or sympathetic. They point out that a strongly positive oculo-cardiac reflex is often noted in these hypertoxic patients. In a paper which appeared recently in the *Journal* Cameron<sup>3</sup> emphasized the importance of damage to the central nervous system as a cause of pulmonary oedema. But in severely paralysed patients it must always be difficult to separate such related predisposing factors as pharyngeal paralysis, with its risk of the aspiration of mucus or even of foodstuffs, and diaphragmatic paralysis with consequent anoxia, which Short<sup>4</sup> regards as an important cause of pulmonary oedema. Because in their view the sympathetic-vagus mechanism is involved, the French workers recommend the use of atropine in such cases. They claim good results with 1-mg doses given five times daily.

The third group in Janbon and Chaptal's series consisted of seven patients who developed acute and progressive pulmonary embarrassment at the time of the late post-diphtheritic palsies. Here they may well be right in arguing that the toxin directly affects the respiratory centre, for in each there was extensive toxic damage in the region of the nucleus ambiguus. Many of their patients seem to have been treated initially at home and to have been admitted to hospital only when the serious complications of

<sup>4</sup> *J. Path. Bact.*, 1944, 56, 355.

the later stages developed. The fact that in this country almost all patients with diphtheria are admitted to hospital at the beginning of the illness may explain why such extensive complications are less frequently seen here.

### HUMAN FACTOR IN AIR ACCIDENTS

Public confidence in the safety of air travel has been shaken by the melancholy succession of disasters to civil air liners, and no flood of statistics about the relatively small number of people killed per million passenger-miles flown can do much to allay the anxiety thus aroused. The investigation of mechanical defects as a cause of flying accidents is pursued openly and effectively, and yet, though the frequency of pilot-error accidents is realized, little is done to disentangle the complex cognitive and emotional basis of the human failure which so often precipitates the catastrophe. The Air Ministry is therefore to be congratulated on its publication of the results of wartime research on this vital subject.<sup>1</sup> What has been learnt about the principles of human behaviour in complex, distracting, and fatiguing situations can be widely applied to accident problems in all hazardous occupations.

At the beginning of the late war the laboratory study of whatever was included by the conventional term "fatigue" was begun in Cambridge under the direction of Sir Frederic Bartlett, and the present monograph by Dr D. Russell Davis describes the results achieved. He used an experimental apparatus designed like an aircraft cockpit, the controls are attached to a mechanism which records the nature, extent, and duration of the pilot's deviation from a prescribed course. It was called the Cambridge Cockpit, and in it pilots were observed while they performed all the manipulation of controls and instruments required in mock flights of varying durations. The analysis of the resulting records showed that, contrary to expectations based on previous work in industrial psychology, there was no simple relation between the duration of the flight and the numbers of errors made. Indeed, errors increased in the first half-hour of the test to reach a maximum during the second half-hour, after which they declined.

Russell Davis found that these errors, and thus the individuals who made them, could be divided into two main groups—errors of overactivity, where a tense individual tends to over-correct his initial mistakes, and errors of inertia where subjects resigned themselves to a lowered standard of performance. Other types of error—specific end deterioration, preoccupation, and perceptual disorganization—were observed, but they were subsidiary to the two main groups, whose importance and significance became clear when the results of these tests were compared with psychiatric assessments of the same individuals. It became obvious that errors of overactivity were an expression of the acute anticipatory anxiety of the neurotically predisposed individual with obsessional trends, while errors of inertia were merely another facet of the withdrawal mechanism of the hysteric. Conclusions based on laboratory experiments do not entirely satisfy the practical flying man, but these were strikingly confirmed by following up the subsequent flying careers of the men tested and by independent studies of operational efficiency. It was found that men in the two "error" groups had an undue number of flying accidents, of failures in training, and perhaps, too, of casualties in action.

The relative unimportance of prolonged activity alone in the causation of accidents was also demonstrated by Bradford Hill and G. O. Williams, who showed that landing

accidents were no more frequent after long sorties than after much shorter ones. Similarly Reid's studies of the effects of operational hazard on navigator efficiency in action and the incidence of neurosis re-emphasized the importance of acute anxiety in the determination of behaviour and performance. In future work on the human problems of industry this example of the synthesis of laboratory and field research might well be followed.

### PENICILLIN IN EXPERIMENTAL SYPHILIS

Recent investigations in the U.S.A. on rabbits experimentally infected with syphilis have shed light on the differences between the various forms of penicillin. It has been recognized for some time that these forms are not alike, but it has not been possible to make a quantitative comparison by clinical observations. A joint report<sup>1</sup> by five groups of workers now states that penicillin G is the most active, that F has about one-seventh the potency of G, and that K has about two-thirds the potency of F. No figure was given for penicillin X. The experiments were carried out by inoculating the testes of rabbits with a virulent strain of *T. pallidum* and treating the rabbits six weeks later with penicillin given every four hours for four days. The rabbits were then observed for 120 days, and from those showing no signs of syphilis a lymph node was taken for emulsification and injection into a normal animal. These were kept for four months to see if lesions developed in which *T. pallidum* could be detected by dark-ground illumination. By this method it was possible to find what percentage of animals were cured by a given dose of a given penicillin. Different workers agreed reasonably well about penicillins G, F, and K.

The duration of the experiment was a disadvantage, and Turner<sup>2</sup> and his colleagues devised a shorter one. Rabbits were inoculated by intracutaneous injection (on the back) with 0.1 ml of an emulsion containing *T. pallidum*. Syphilomas appeared in 14–21 days, and on a given day a drop of serum from the middle of the syphiloma was examined by dark-ground illumination and the number of visible motile organisms counted. The penicillin to be investigated was then given by intramuscular injection in three doses at two-hourly intervals. The number of motile organisms in a drop of serum from another syphiloma on the same animal was then determined after 24 hours. Each dose of each kind of penicillin was given to a group of rabbits so that the mean effect could be calculated. The final result was that penicillin G was most active, that F had about one-sixth the activity of G, that X was about equivalent to F, and that K had less than one-fifth the activity of F. These relative values were on the whole similar to those obtained by the longer method.

In other interesting investigations Eagle, Magnuson, and Fleischman<sup>3</sup> compared the action of penicillin in rabbit syphilis with that of a combination of penicillin and heat. They found that when the body temperature of the rabbit was increased by 3° to 4° F (1.8°–2.4° C) for a period of about 10 hours during the administration of penicillin the curative dose of penicillin (in 50% of the animals) fell from 30,000 to 3,000 units per kg body weight. The authors believe that the rise in temperature reinforces the action of the penicillin, because observations on *treponemata in vitro* do not suggest that such a rise of temperature has any lethal action itself. The same authors<sup>4</sup> have also measured the increase in the curative power of penicillin in rabbit syphilis brought about by adding beeswax to a solution of

<sup>1</sup> *Amer. J. Syph.*, 1947, 31, 469

<sup>2</sup> *Ibid.* 1947, 31, 476

<sup>3</sup> *Ibid.*, 1947, 31, 239

<sup>4</sup> *Ibid.*, 1947, 31, 246

calcium penicillin in arachis oil A required curative dose of 39,000 units per kg, given daily for four days, fell to 8,000 units when 3% beeswax was added, and to 3,500 units with 6% beeswax

### THE PHANTOM LIMB

A number of our correspondents have discussed recently the problem of pain in "phantom limbs," and there is a further contribution to this discussion at page 267 of this issue. The symptoms which follow amputation of a limb are so incompatible with the ordinary dictates of common sense that it is small wonder that most amputees prefer to keep discreetly silent about them. Even standard textbooks still generally dismiss the subject in a few embarrassed phrases or omit it altogether.

It is now established that phantom sensations are a physiological sequence of all major amputations, the pattern of subjective phenomena being remarkably constant.<sup>1,2,5</sup> Immediately following amputation the patient is aware of the continued presence of the lost member, generally in a comfortable relaxed position, and he usually feels that he is able to "move" the limb normally. During the months of convalescence the phantom progressively "shortens," until it may feel only a few inches long. Sensation from fingers, toes, and joints persists longest and most vividly, so that ultimately a phantom arm may be experienced as only fingers, wrist, and elbow, with no intervening forearm. By this process a relatively intact central nervous system adapts itself to a profound bodily change, and it is an entirely normal physiological occurrence. In W R Henderson and G E Smyth's recently reported series<sup>2</sup> of over 300 prisoners of war who had undergone major amputations only about 2% "asserted that they had never felt a phantom", it may be that these men rejected the possibility much in the manner of Craig's<sup>3</sup> patient who, having a painful phantom, did not at first report sick because he "did not expect a doctor to treat a ghost". The painless phantom is of little importance to the patient who is reassured that his experiences are perfectly normal, and their chief interest lies in the light they cast on the functioning of the nervous system.

Amplifying the body-image concept of Head and Holmes,<sup>4</sup> Riddoch<sup>5</sup> suggested that there are normally three integrated "body images" in the sensorium—visual, motor, and sensory—in terms of which all movements are initiated and all sensations interpreted. The loss of a limb does not at first impair the sensory or motor patterns which help to constitute the compound body image. The limb still persists in the sensorium, it is still remembered, and so it can be felt and "moved" as though still present. With passage of time the cortical elements formerly concerned with the lost limb cease to play a role no longer useful, and they probably take over other functions. Accordingly the phantom becomes "telescoped". The fingers, joints, and toes, having the largest cortical representation, persist longest and most clearly.

The phantom limb which is painful presents a much more difficult problem of immediate practical importance. Reports differ about the frequency with which such pain occurs, and probably the criteria adopted by the authors and their patients in assessing actual pain have not been

the same. The very low incidence—about 4%—reported by Henderson and Smyth may be due to the distinctive type and age group with which they dealt. Riddoch believed that phantom pain followed about 50% of amputations, Shosberg<sup>6</sup> puts the figure at about 70%, while Craig considers that some pain is almost invariable, generally diminishing in intensity and frequency spontaneously, so that only a small proportion of patients overcome their natural reluctance and seek medical advice.

Formerly the pain was believed to arise in neuromata growing in the stump, but it is now known that such growth is normal and that the amount of pain experienced bears no constant relation to the state of the stump. It is probable that these cases are examples of causalgia similar to that which may follow any nerve injury.<sup>3,7,8,9</sup> Pain so produced is felt in the phantom, just as deep pain, skeletal or visceral, may be projected to a phantom arm or leg.<sup>10,12</sup> The pain of angina pectoris may, for example, spread to a phantom left arm.

Unless there are obvious defects in the stump, or pressure of the prosthesis on a superficial neuroma is producing troublesome pins and needles, remodelling operations are generally of little benefit. Persistent severe pain can frequently be relieved by procaine sympathetic block, and it may not return for weeks or months, when the procedure can easily be repeated. The duration of the period of relief tends to increase, so that complete cure may follow three or four injections. Not until all such simple methods have been tried should more drastic treatment be considered. It is important at all times that the patient should see that his strange symptoms are accepted as being real, as indeed they are.

### INTERNATIONAL STUDENTS' CONFERENCE

The British Medical Students' Association is to be congratulated on its enterprise in holding recently what is believed to be the first international congress of medical students, a report of which appears on page 265. Over 100 delegates from 24 countries, including 30 from Britain, met successively in London, Oxford, and Birmingham from July 6 to 22 to study many aspects of British medicine—clinical, laboratory, industrial, and public health. When books and journals are difficult to obtain and currency restrictions in many countries impede the traveller, conferences such as this assume an added importance in promoting the free exchange of medical knowledge. There is no better way of broadening a young man's education than by giving him the opportunity of meeting colleagues from abroad and studying their methods. The mere fact that he is in strange surroundings stimulates him to examine them carefully, and the high prestige enjoyed by British medical science in the post-war world invites the close scrutiny of its achievements.

When the B M S A was founded in 1941 to promote interests of students it was recognized that clinical conferences, both national and international, would be one important means of fulfilling this aim, and students in the country accordingly hold several conferences every year in London and the provinces. A teaching centre in students from one or more other regions and takes considerable trouble over displaying its wares attractively, helping to mitigate the over-specialization deplored by Professor Ryle's address read at Oxford. We should let the occasion pass without complimenting those main teachers and authorities on special subjects who enthusiastically contribute to the success of these meetings. Time is well spent, for as one student said<sup>1</sup> at the conference held in 1943, "We are still young enough and daft to work for a future that will be better than the present."

## ATOMIC ENERGY RESEARCH ESTABLISHMENT PROGRESS AT HARWELL

Much of the work of the Ministry of Supply's Atomic Energy Research Establishment at Harwell was revealed at a series of demonstrations last week. This establishment was founded in November 1945, to carry out fundamental research and development in atomic energy, and three months later Professor Sir John Cockcroft was appointed director. Since then two experimental nuclear piles have been brought into operation, the production of radio isotopes has begun and much progress has been made with the installation and testing of equipment. The establishment comprises seven divisions each comparable in size to that of a large university research department. Harwell is a former R.A.F. station, and all the hangars and most of the buildings have been adapted to its new function. Each of the two nuclear piles has been constructed within a hangar and a tower built originally for navigational training is being used temporarily to accommodate high-voltage equipment. The following aspects of the work of the establishment are of specifically medical or biological interest:

1. The production and distribution of radioactive isotopes for research and therapeutic use.
2. The separation of stable isotopes for research use.
3. The protection of the health of the workers in the establishment.
4. The prevention of contamination of Thames water by radioactive substances in the effluent from the establishment.

In addition the Medical Research Council has established a radio biological research unit at Harwell to investigate the effects of radiation on different types of living matter. This group is now building up its facilities and staff. As a supplement to the routine health services of the establishment—which are the responsibility of the Ministry of Supply—it is to investigate the possible effects on the staff of continuous exposure to weak radiation as well as the effects of large doses of radiation, and to evolve counter measures.

The working of a nuclear pile and its use for the production of radio isotopes have been described by Chadwick<sup>1</sup> and the properties of particular isotopes by Mitchell<sup>2</sup> while their uses in research and therapy have been more lately discussed by the Radiology Section at the Annual Meeting of the British Medical Association<sup>3</sup>. In brief a radio isotope is a radioactive form of a chemical element which is normally stable. It behaves chemically as do stable isotopes of the same chemical element, emits beta particles or gamma radiation or both from which its presence can be identified and has a half-life (period of decay to half-intensity) varying from a fraction of a second to thousands of years. Radio isotopes may be produced either plentifully in a nuclear pile or in smaller quantities by the bombardment of normal stable isotopes by high-energy particles from an accelerating device of which a cyclotron is at present the most practical for the purpose. Most radio-isotopes can be produced in a nuclear pile and the cyclotron method would only be used to meet some particular requirement which the pile could not undertake.

Radio isotopes are formed by the fission of the uranium atom—that is by the same process by which energy is released in nuclear piles. But owing to the fact that the uranium atom can split in a large number of different ways, the result is a mixture of radioactive atoms of many elements. These are formed in the uranium rods which are part of the structure of the pile and for most purposes have to be chemically separated before they are of use. Since the level of activity may be extremely high this is a difficult undertaking and is not the method of choice. The more usual method is therefore to expose special containers to neutron irradiation within the pile and provisions made in the design of the pile for this method of production

### The Nuclear Piles

Two piles are at present in operation at Harwell. The first, the gleep (graphite low energy experimental pile) came into operation in August 1947 and has a power output of 100 kilowatts. Externally it appears as a large concrete cube of the height of a substantial three-story building and the only sign

of activity is in the control room, which except for variations in the instruments used might equally well be that of any other plant to which electrical methods of recording and control are applied. Inside the five-foot thick walls of protective concrete is a cylindrical structure composed of rods of pure graphite and uranium arranged axially. This is the pile proper. The control rods, which limit the activity of the pile, are lowered into it from on top. Half-way down the main cylindrical structure there is a clear space in the horizontal plane into which a further graphite bar can be inserted, in this bar there are a number of holes to take the containers to be irradiated.

The second Harwell pile, with a rated power output of 6,000 kilowatts, has only lately come into operation and is at present at the testing stage. It is a slightly larger structure than the gleep, and differs principally from its predecessor in the greater amount of air cooling which has been provided. Because of this it can be run at a power output sixty times greater, and larger amounts of material can be irradiated. In place of one irradiation channel there are forty, but the general arrangement is the same, with the irradiation channels running from side to side through the main structure.

Irradiation is carried out in aluminium containers. In the gleep these are cylinders of 30 ml volume and of about the same cross-section as that of a halfpenny. These containers are inserted in graphite blocks of rectangular cross-section, each of which is drilled with eight holes of the same size and shape as the containers. Larger containers may be used in the new pile. Duration of irradiation depends on the radio-isotope which is being produced, the degree of activity required, and the intensity of radiation within the pile. Typical figures in the case of the gleep are: sodium or potassium, a week-end, iodine, a fortnight, sulphur, a month, calcium, three or four months. With the new pile times will be reduced and quantities can be increased, and it will be possible to extend supplies to members of the Commonwealth and other overseas countries. The production of radio-cobalt (cobalt<sup>60</sup>), which offers promise as a therapeutic substitute for radium, is to be undertaken at an early stage, and it was stated by Sir John Cockcroft that amounts equivalent in gamma-radiation to 100 g of radium could be readily produced if required.

### Cyclotron Production

Like the two piles, the Harwell cyclotron (Fig. 1) is being built in a hangar. It consists of a 700 tons magnet, with poles 110 inches in diameter between which particles will be whirled round and accelerated to energies of 200 million volts. It is expected that it will be completed about the end of this year, in effective use by April, 1949, and that for some years thereafter it will remain the most powerful British equipment of its type. It is primarily intended for nuclear research, but will also be used as required to produce particular radio-isotopes which cannot be made in the two piles.

Most radio-isotopes produced in the piles are obtained by irradiation of the same chemical element which it is desired to obtain in radioactive form. In these cases no further processing is required, and after removal with long forceps from the graphite blocks the containers can be transferred direct to lead containers. In a few cases chemical separation is necessary, and this is true generally of radioactive material resulting from the fission process. For this reason, as well as for the separation of the plutonium formed in piles, it is necessary to provide special chemical laboratories where all operations are performed in fume cupboards with a high rate of air-exhaustion and behind protective walls built up from interlocking lead bricks. The present chemical laboratories are in a converted barrack block. But because of the special problems which will arise when larger quantities of materials are being handled a new "hot" laboratory is being built of a size comparable with that of many complete research institutions. Only the ground floor of this building will be in normal use, the whole of the upper floor being occupied by the ducts of the ventilating system and servicing provision. The two active wings are separated from the central offices by vestibules and changing-rooms, in which the air pressure will be maintained at a slightly higher level than in the laboratories.

Fig 1—General view of 110 in (275 cm) cyclotron magnet during erection. The magnet contains 700 tons of steel. Some of the copper windings have been installed on the lower pole. There will be six pairs on each pole when the magnet is completed, containing a total of 70 tons of copper. At maximum power a current of 600 amps at 500 volts is passed through the coils. The gap between the pole faces in the picture is 40 in (1 m). When the magnet is completed this will be reduced to 12 in (30 cm), and it is in this gap that protons or deuterons are accelerated. (Crown copyright)

Over a hundred specimens of radioactive isotopes have been dispatched in each month from March, 1948, onwards. Laboratories and institutions which have received supplies include the following: the Medical Research Council, the Christie Hospital, Manchester (for cancer research), Manchester University (chemistry of anaesthetics), the Royal Cancer Hospital, the National Centre of Radiotherapy (heart diseases), Cambridge University (cancer), University College (biophysics), University College Hospital (blood research). Other British research uses have covered such varied applications as chemistry, physics, photographic films, mechanical friction, textiles, fertilizers, and plant growth. Supplies have also been sent to users overseas.

In general it is expected that bulk supplies will be distributed through the Radiochemical Centre at Amersham, and that individual research requirements will continue to be met direct from Harwell in a large proportion of cases. An advisory service on the experimental use of radio-isotopes is being provided, and arrangements are also being made whereby research teams from the establishment can carry out experiments for the user on the user's premises. This is primarily intended for industrial applications, but it might also be helpful in the medical field. It means, at any rate, that the use of the radioactive tracer method will not necessarily be confined to institutions which themselves possess the required specialized staff and facilities.

Stable isotopes differ from one another only in the mass of their atoms, and, like radio-isotopes can be used in "tracer" research, though more difficult techniques are involved. There is a considerable demand for the carbon isotope of mass 13, and an experimental plant is being built for its separation from normal carbon. The process adopted makes use of a small difference of about  $2.0^{\circ}\text{F}$  ( $1.1^{\circ}\text{C}$ ) in the boiling points of liquid carbon monoxide containing the two isotopes. The plant will be complete in a few months' time, and will produce carbon 13 at a rate of about 0.3 g per day by the end of the year. This is expected to be enough to meet immediate demands. Work is also being done on three other methods of separation.

### Health Services

The essential problem of the health service at Harwell is to ensure that no members of the staff are exposed to excessive radiation. This is done by a combination of individual monitoring, permanent local monitoring in active areas, and further

surveys, including the taking of air samples, as required. The standard adopted, which was recommended by the Medical Research Council, is that the total integrated dosage of the individual should in no case exceed 0.5 r per week, but the present average for the establishment is less than one-fifth of this figure. This includes gamma radiation, beta particles, and fast and slow neutrons, and in area surveys these are measured separately and added together.

Individual monitoring is based on the use of three different types of recorder. The first, carried by all workers liable to exposure, is a radiation-sensitive pocket film. These are collected weekly and forwarded to the National Physical Laboratory for development under controlled conditions. Films showing more than the usual darkening are reported by telephone. The routine reports are plotted for all individuals as a weekly record of radiation received. The two further types of individual recorder are for more immediate ascertainment of dosage rate where this appears desirable. The simplest type, comparable in size with that of a nasal inhaler, is a pocket condenser. This is charged to a prescribed voltage, and is gradually discharged by exposure to radiation. Measurement is carried out in the laboratories of the health physics group. The third type of instrument resembles an overgrown fountain-pen, and with it the individual recipient can make his own observation of dosage received at any time. It is an

electroscope of the Stephen type in which a quartz fibre is deflected electrostatically from a metal plate. Both these two instruments can conveniently record a dosage rate one-tenth of the average permitted.

Fixed radiation meters are provided for the measurement both of integrated dosage and of the current dosage rate. The scale of the former is calibrated in hours, the permitted dosage for a day's work corresponding with a reading of 8 hours. A glance at the "clock" is thus sufficient to inform the individual

Fig 2—Pistol monitor. This is typical of the portable health instruments employed in work with radioactive substances at Harwell. It can be used to measure the intensity of either beta or gamma rays in laboratories and elsewhere. (Crown copyright)

worker in such an area whether he is above or below the acceptable rate and, if necessary, he will transfer his activities to a less active area. The current dosage meter is intended to guard against unduly high temporary radiation and can be set to sound an alarm at a predetermined level. Both types of meter add together the combined effect of different types of radiation which for this purpose are separately recorded.

Area monitoring includes the checking of radiation levels with portable instruments (Fig 2) the taking of air samples, the checking and maintenance of all health instruments, and the demarcation of restricted areas to which access by unauthorized persons is forbidden.

The Medical Division is responsible for the health of all workers in the establishment. All are given a full examination when joining, and this is repeated periodically. All workers exposed to radiation have regular blood counts, but since no case of over exposure has yet occurred the blood examinations are regarded rather as in the nature of insurance.

### Prevention of Contamination

The permissible standard of radioactivity in water returned ultimately to the Thames is described as being such that the medical and biological effects "due to the consumption of water during the life span of human beings would be for all practical purposes negligible." The tolerance adopted was laid down by the Medical Research Council, and control is in the hands of the health physics group of the establishment.

Water is to be separated for disposal purposes into three categories. The most highly active is removed and not returned to the Thames. The second category is treated as described below, and the third, which has been used for cooling and domestic purposes is mixed with the second on the last stage before disposal. The sequence of treatment for water in the second category is as follows. In the first stage it is pumped rot gravitally fed, into one of two 300,000 gallon tanks built of acid resisting brick. In the next stage it is chemically neutralized. Thirdly sludge containing a large proportion of the radioactive material is mechanically separated, pressed into solid cakes, and retained. Finally, the water thus treated is mixed with "safe" water and sampled before discharge. The whole process will extend over three weeks.

## STUDENTS' INTERNATIONAL CLINICAL CONGRESS

### MEETINGS IN LONDON, OXFORD, AND BIRMINGHAM

What is believed to be the first international gathering of medical students was held successively in London, Oxford, and Birmingham from July 6 to 22. The idea of an international clinical congress of students was put forward at Prague two years ago when delegates from the British Medical Students Association were present, and that body undertook the responsibility of organizing a British meeting in 1948. The Congress was attended by just over 100 students from 24 countries. The number of accredited delegates from Great Britain was 30, one from each medical school.

On the afternoon of their arrival in London the visitors were entertained at a reception at B.M.A. House, when Dr Charles Hill gave a description of the National Health Service. Later the President of the B.M.S.A., Mr Stephen Drancz, of Edinburgh welcomed them saying how much British students were looking forward to this international exchange. A suitable response was made by an American student, and the Congress was formally opened by Mr Zachary Cope who spoke of it as reviving in a new form the habit of the Middle Ages when students travelled to the places of learning in one country or another.

### A Flexible Programme

The programme on which the students then entered was different in each of the three centres visited. In London the typical British method of bedside teaching with rounds, out-patients, and lectures, was followed and the students spent two whole days in one or other of four hospitals—London, Middlesex University College or St Mary's. Small groups also visited some twelve special hospitals as well as the laboratories of

pharmaceutical firms. The London week ended with a lecture-demonstration at the National Hospital, Queen Square, a visit to the Royal College of Surgeons, and a reception by the British Council. A "film festival" at the Wellcome Institution was an evening feature.

At Oxford, where the Congress was welcomed by the Regius Professor of Medicine and entertained at Magdalen Hall, the general theme was "Recent Advances in Medical and Surgical Research," and lectures and demonstrations were given by Sir Howard Florey on antibiotics, Professor R. R. Macintosh on anaesthetics, Professor Chassar Moir on analgesia in childbirth, Sir Hugh Cairns on pyogenic and tuberculous meningitis, and Professor L. J. Witts, Dr J. Truett, Professor R. G. Macfarlane, Dr A. H. T. Robb Smith, Dr Isaac Berenblum, and others on their special subjects. The departments of physiology, anatomy, biochemistry, and social medicine were visited, and one evening was devoted to a showing of medical films, including one of the Blalock operation for pulmonary stenosis. One of the discussions, presided over by the Dean of Oriel, was on food problems in post-war Europe. The concluding address at Oxford was given by Professor A. D. Gardner, of the School of Pathology.

The four days at Birmingham, where the students were welcomed by Sir Leonard Parsons, Dean of the Faculty, and also attended a civic reception given by the Lord Mayor, were spent in attending demonstrations on aspects of industrial medicine and public health. The United Hospitals, the Accident Hospital, and the clinics of large factories were visited. An afternoon was devoted to a discussion on the National Health Service and local government services, and the Birmingham functions concluded with a dinner given by the University Medical Society.

### The Presidential Address

The shadow on the Congress was the illness which prevented its president, Professor J. A. Ryle from taking part and leading the Congress at Oxford. He wrote that he had pleaded with his doctors to be allowed to attend this event even if it meant breaking many engagements in the coming months, but his advisers were adamant and he knew that they were right. In his presidential address, which formed part of the proceedings, Professor Ryle discussed the growth of specialization—such a steady growth that "alas, the general physician of the type who taught me and my father at Guy's has become a *rara avis*." In many directions, of course, knowledge and the treatment of the sick had been very greatly advanced by all the new technologies and skills, but a stage had now been reached in which it could be said, with equal justice, that the teaching of students and the practice of medicine had in the process quite considerably suffered. The logical attitude and thoughtful integrations of ideas and subjects were tending to go by the board. The new technology and over-specialization had led too often to a neglect of the philosophy which could co-ordinate all our sciences and methods. "We have, in brief, gone astray in no small measure because of the multiplicity of our new tools and tests and our impatience to employ them. Meanwhile we are suffering—and our patients with us—from a very serious dearth of men and women with a physicianly training and physicianly minds, of men like the old *chef de clinique* and the good family doctor, of men like Balzac's hero in *Le Medecin de Campagne*."

Although the days of the Congress were full of work, the evenings were mostly devoted to pleasure. Among other events were a buffet supper given by the British Council, a sherry party by the Royal College of Physicians and a concert by the St Mary's Hospital Musical Society. Visits were paid to Windsor, Hampton Court, and Stratford-on-Avon, and at Oxford the river was an attraction. At Birmingham the president of the Medical School, Dr H. W. Feathers, gave a garden party at his country house.

Congratulations were tendered to the Organizing Committee of the B.M.S.A., under the chairmanship of Mr H. E. Reiss, who carried through this ambitious programme, and appreciation was expressed of the co-operation of the medical schools and hospitals at the centres, the British Medical Association, the Royal Colleges, the British Council, and the International Union of Students. Mr B. Wainfield, the chairman of the Medical Faculty Bureau of the International Union, said that the Bureau

would be instructed by the Congress about the activities to be organized in order to help to solve the problems the Congress had been discussing. The I.U.S., representing the overwhelming majority of students throughout the world, had the task of serving the needs and defending the interests of students everywhere, and the Clinical Congress was both an end and a further means through which the International Union could best fulfil this responsibility.

## BRITISH EMPIRE CANCER CAMPAIGN

### AWARD TO PROFESSOR E C DODDS

The twenty-fifth annual meeting of the British Empire Cancer Campaign was held in the Moses room of the House of Lords on July 19, Viscount Hailsham presiding. The "Garton" medal and prize (£500) was presented to Professor E C Dodds for his contributions to cancer research, notably the synthesis of stilboestrol. Professor Dodds, after acknowledging the help of many collaborators, returned the £500 as a contribution to the Campaign's special appeal.

A delegation from the Campaign, led by Lord Horder, has been visiting Canada and the United States to strengthen the bond between cancer research organizations on both sides of the Atlantic. A cablegram from Lord Horder was read stating that their welcome had been most cordial, and that valuable contacts and observations had been made at both research and organizational levels.

It was reported that the Campaign's expenditure on research was steadily increasing, and that before the close of 1947 over £110,000 had been already voted for application during 1948.

Mr J P Lockhart-Mummery, who has edited the annual report during the entire existence of the Campaign, presented the report for the year 1947. He mentioned that from headquarters alone, without counting the branches, there had been allocated during 25 years a grand total of over £1,000,000 sterling to research centres and individual workers. "We have almost completely succeeded in one of our original aims—namely, the co-ordination of cancer research. Where, 25 years ago, one man was devoting his time and energies to cancer research, there are hundreds doing so to day, and we hope soon greatly to increase this army of investigators." Of the new chemical substances tried for the control of cancer, the most notable was stilboestrol, which in suitable cases could control cancer of the prostate gland, urethane appeared able to control leukaemia. The study of the minute structure of the healthy and the cancerous cell had made great progress as a result of the use of the electron microscope, and it began to look as though some of the important secrets of the cancer cell and the way in which it developed would not much longer elude us. More electron microscopes were badly needed, they were expensive instruments, costing about £3,500 apiece.

### Reports from Research Centres

The annual report, which was adopted by the meeting, contains accounts of their year's work by some 19 research departments, as well as reports from a number of individual workers and from institutes and foundations in the Dominions. Every year the Clinical Cancer Research Committee presents a statistical analysis of cases of cancer in some part or organ, this year it is on 126 cases of cancer of the kidney, 451 of the bladder, and 399 of the prostate. A report is included from the Marie Curie hospital on the radiological treatment of 1,900 cases of carcinoma of the cervix of the uterus, 1,580 of which were treated some five years ago.

The reports from the research centres this year seem to pay more attention to radiological methods than usual. Some account is given of the investigation of high-energy radiations, carried out under the aegis of the Medical Research Council by the staff of the departments of physics and chemistry of the Royal Cancer Hospital. This relates to the use of the 14 Mev synchrotron at the Telecommunications Research Establishment, Malvern. Preliminary work has been done on the development of techniques for measuring the radiations in roentgens, the precautions necessary to obtain satisfactory beams, and the ascertainment of the distribution of energy to be expected in the body at these voltages. At the Christie Hospital and the Holt

Radium Institute, Manchester, work is proceeding on the association of urethane with x rays in the treatment of neoplastic diseases, and at the Cambridge University Research Centre another chemotherapeutic agent is being studied as likely to be of value when combined with radiotherapy in treatment, this is the compound known as tetrasodium 2-methyl-1,4-naphtho-hydroquinone, which is of low toxicity and exhibits vitamin-K activity, though such activity has probably no relevance in this application.

The problem of carcinogenesis is being attacked on many sides. The relationship of sex hormones and carcinogenesis, the histogenesis and histopathology of the tumours induced by acetylaminofluorene in the lungs of rats, and the possibility of a biological "chain reaction" in skin carcinogenesis are lines of work which are being pursued in the Chester Beatty Institute of the Royal Cancer Hospital, the Department of Pathology at Sheffield, and the Sir William Dunn School at Oxford, respectively. At Glasgow Royal Cancer Hospital the question of overheated foods has been studied. Evidence points to some unidentified carcinogen present in fats heated to 300° C or more. Various irritants used as condiments have been tested for possible co-carcinogenic activity, but so far without positive results. With the help of several large restaurants, supplies of heated-fat residues from ovens and frying-pans used in large-scale cooking have been obtained and subjected to chemical fractionation and spectrographic and other analysis, but no known chemical carcinogens have been detected in any of these materials.

Another interesting point comes out of some research by Sir Ernest Kennaway and others in the Pathology Department of St Bartholomew's. The question of the prevention of cancer of the penis by circumcision in the Jewish manner on the eighth day of life has been examined, and no record has been found of any case in which this protection has failed. On the other hand, cancer of the penis occurs in Moslems, among whom the operation is performed between the third and fourteenth year. Records, all from the United States, of 16 cases of cancer following surgical circumcision by methods of the present day have been obtained. The operation was carried out at ages from 14 to 45, and cancer developed after an interval of 8 to 41 years (average 23). It is suggested that the failure of this operation when deferred until the fourteenth year to give the protection afforded by it when carried out on the eighth day may mean that the train of events leading to malignant growth is set going early in life, and that subsequent removal of the cause does not then avert the development of cancer at a much later age. This principle may hold good in other forms of cancer, which, arising in the second 25 years of life, may have been predestined to occur by factors to which the body was exposed during the first 25 years. The idea is of interest in connexion with the possibility of preventing cancer by attention to the hygiene of youth.

## THE KING'S FUND

King Edward's Hospital Fund for London, which has now entered its second half century, held its annual meeting at St James's Palace on July 9, when the Duke of Gloucester presided. The transfer of hospitals to the State, said His Royal Highness, was not the only—perhaps not the most important—change that was taking place in the hospital world to day. That world was in the throes of evolutionary developments, the outcome of which no one could foresee. New conceptions of hospitals as a system closely integrated with medical practice and with preventive and social welfare activities were abroad, and these in their turn reacted upon the position of the Fund. The Duke suggested that it now became a Foundation rather than a Fund, and he went on to say that the Fund was establishing relations with the great foundations of America those bearing the famous names of Rockefeller and Kellogg, and also the Commonwealth Fund—which were playing a part as pioneers in the hospital world, and it might be some modification of the machinery of the Fund on the part of these American foundations would prove to be convenient. The word "Fund" in the title of this organization has been entirely appropriate. The King's Fund has been more than a mere grant-distributing agency. Its activities

connexion with district nursing with nursing recruitment with hospital diet catering and domestic supervision and with the emergency bed service are well known. In the new hospital arrangements its function as an agency of distribution although it will continue may be expected to bulk less largely in comparison with other activities. But it is no small advantage to have an organization with such large resources under its own control giving a guarantee of freedom and elasticity to the new Service. It will encourage voluntary work in that large field which lies just beyond the border of State provision and as the annual report states it will be open to hospitals in the metropolitan area whether teaching hospitals or those coming under the four regional boards, in any matters which are experimental or which seem to go beyond the normal activity of a hospital under the Act, to lay proposals before the Fund and seek its assistance.

In 1947 although the National Health Service Act was already law and the shape of the hospital service was clearly seen a sum of £34 000 was contributed to the King's Fund by subscribers and donors. This however, is only about one-tenth of its total income, which comes mainly from investments. The ordinary distribution to 145 hospitals and 53 convalescent homes, was £203,250. Until it has been decided how the resources of the Fund can be most usefully applied, a conservative policy may be necessary but the Fund is looking forward not to restriction but to increased opportunities. Among the immediate activities are the inauguration of an information service, the continuation of bursaries for the training of hospital administrators and the establishment of new bursaries for hospital almoners, and the setting up, in consultation with the Ministry of Health and the Royal College of Nursing of a resident training course on new lines for those about to take up posts as ward sisters.

## Nova et Vetera

W G GRACE

William Gilbert Grace was born on July 18, 1848, and fifteen years later achieved prominence as a cricketer when he scored 32 runs in a match against the All-England Eleven. He was the fourth son of Mr. Henry Mills Grace, who practised as a surgeon at Downend near Bristol, and was himself an ardent cricketer. His uncle, Alfred Pocock, and his father introduced him at an early age to the delights of our national sport, and when only nine years old he played for West Gloucestershire against Badminton. At the age of 17 he played twice for the Gentlemen v. Players being selected then for his prowess at bowling rather than batting, and thereafter continued to play in first-class cricket until 1900. In first-class matches his highest score was 344, made in 1876 for the MCC against Kent; two days later he made 177 for Gloucestershire v. Notts, and two days after that 318 not out for the same county against Yorkshire.

Endowed with a splendid physique—he stood 6 ft. 2 in., and was powerfully built—W.G. excelled also at running and hurdling and two days after scoring 244 not out for England v. Surrey in 1866 he won a race at the National and Olympian Association meeting at the Crystal Palace. Commenting on Grace's fine physique Dr. Clippendale pointed out that the surname derives from the French "Gros" a sobriquet originally bestowed on men of large stature. As soon as the cricket season was over he threw himself energetically into sports more adapted to the English winter—running with the beagles, hooting, and hunting.

Grace qualified in 1879 with the LRCP of Edinburgh and the MRCS of England and practised at Bristol until 1899, being at one time medical officer to the Barton Regis Union, accinator to a district in the union and surgeon of the Pennwell Collieries. In that year he gave up practice and moved to Sudenham to become secretary and manager of the London County Cricket Club. He died of heart failure after a short illness in 1915.

## Correspondence

### Pain in Phantom Limbs

SIR—The correspondence in your columns on this subject has been extremely interesting. It seems possible that the disappointing results from the treatment of this condition may be due in part to a failure to appreciate that at least two distinct types of phantom limb pain may occur in amputation stumps. The presenting symptom of pain may be (1) a painful paraesthesia associated with a tender neuroma, or (2) causalgia. It is to Weir Mitchell that we owe the term causalgia and it is clear from his writings that he restricted the use of the term to the immoderate burning pain which is a *sine qua non* of the condition. Modern usage has extended the term to include the peripheral manifestations of the syndrome (coldness, hyperidrosis, hyperalgesia).

Phantom limb pain may be of a causalgic type and give a typical history, but on the other hand and much more commonly, it may take the form of painful paraesthesia. This latter type of pain is quite different from that of causalgia, being of a stabbing, shooting, or tingling quality, in which the characteristic burning of causalgia is absent. Reference of pain to the phantom limb occurs in both types of case. Some degree of paraesthesia is common to all neuromata whether of amputation stumps or of peripheral nerve injuries and in the large majority it can only be elicited by an obvious mechanical stimulus of the neuroma. Associated with this "stump tenderness," however, may be a paraesthesia of a much more serious and disabling nature, which occurs—apparently spontaneously—as a result of the constant irritation of regenerating sensory nerve fibres which are sprouting freely into the scar tissue from the cut end. This type of phantom limb pain, the aetiology of which is mainly if not entirely peripheral, can usually be relieved by a careful resection of the neuroma with or without reamputation of the stump. It is unlikely to be affected by sympathectomy. On the other hand, unfortunately, the causalgia is very seldom if ever cured by local operative procedure alone.

A minute investigation of the history of the onset and evolution of the pain, of its quality, and of its aggravating and relieving factors should help to differentiate between the two types and thus act as a valuable guide to the form of operation most likely to prove successful.—We are, etc.,

R E M BOWDEN  
J R NAPIER.

### Short Leg

SIR—May I reply to the interesting letter of Captain Robert Fuller and Lieut. Douglas L. Woolf (July 10, p. 109)? The first thing to decide when the examination of a patient reveals a short leg is if the shortening is real or apparent. A real short leg will cause a tilting of the sacral top and is bound sooner or later to lead to a scoliosis with the convexity towards the shorter leg. In that case a lift under the short leg, sufficient to make the sacral top level, will be indicated. If, however, the shortening is due to fixed backward rotation of the ilium on the sacrum a lift will make the sacral top level, but will at the same time make the backward rotation of the ilium permanent. The resultant ilio-sacral strain is one of the most fruitful causes of chronic backache. The rational treatment of this type of short leg is forward rotation of the ilium by manipulation, which will equalize the length of both legs, make the sacral top level, and either prevent a scoliosis or, if it has developed, bring the lumbar spine into normal alignment.

There are two methods to decide if the shortening is real or apparent. The one is a standing AP x-ray of the pelvis and lumbar spine. If a thin wire exactly parallel with the floor or the surface on which the patient is standing while the film is exposed is fixed across the Potter-Buckley differences in the level of the trochanters, femoral heads and acetabula down to 1/4 in. (0.63 cm.) or even less can be easily appreciated. The second method is of help only indirectly in so far as it helps to determine the range of mobility of the sacro-iliac joints in a given case. A short left leg, for example, may be due to a

forward rotation of the *right* ilium on the sacrum, with an apparent lengthening of the *right* leg. In that case again a lift under the short leg would be contraindicated. The correct treatment would be manipulative backward rotation of the right ilium, which will result in equal length of legs and levelling of the sacral top. To decide if a shorter (or longer) leg is due to a backward (or forward) rotation of the ilium the test described by Downing is invaluable. If my memory serves me right it is also mentioned in Menell's book on backache. It has been out of print for years and I do not possess a copy—I am, etc.,

Bristol

H WOHLFELD

### Repair of Indirect Inguinal Hernia

SIR—Vr E S R Hughes and Mr J T Fathi (July 17, p 135) record an interesting observation on the anatomy of the internal ring in cases of indirect inguinal hernia, and the refinement of technique which they introduce is worthy of attention. A sentence in their opening paragraph, however, invites comment. They state "It is this weakness [at the internal ring] that may account for the high percentage of indirect herniae as well as their early reappearance after operation." This can only be taken to mean that a high proportion of "recurrence" after operations for indirect hernia occur at the internal ring. This appears to have been the case in those operated upon in the Services during the late war, a fact which has coloured much recent writing on the treatment of inguinal hernia.

In twenty years of civilian practice I have encountered my fair share of "recurrent" herniae, and almost without exception a direct hernia has been found in Hesselbach's triangle with no hernia at the internal ring. The discrepancy is possibly accounted for by the observation made in the Service cases that the sac had been left behind or incompletely removed at the first operation.

It is questionable whether a post-operative hernia in Hesselbach's triangle after radical cure of an indirect hernia should properly be called a "recurrence." Though the term is useful in that it reflects the patient's probable view of the matter and that it fastens the responsibility on the surgeon, it is misleading in that it obscures the pathology. The fact that the great majority of acquired inguinal herniae, whether post-operative or otherwise, are *direct* shows that in the absence of a patent processus vaginalis Hesselbach's triangle and not the internal ring is the weak point of the inguinal canal.

The moral surely is that to avoid post-operative hernia attention must be concentrated on reinforcing the medial part of the posterior wall of the canal, and that plastic procedures applied to the site of emergence of the spermatic cord at the internal ring are at most of only secondary importance.

If a relieving cut is made in the internal oblique aponeurosis well above its lower free border and extending well into the rectus sheath, a stitch firmly uniting its medial end to the periosteum of the pubic spine will hold the conjoint tendon down so that it lies practically in apposition with Poupart's ligament. These two structures can then be united by a row of stitches which do not need to be so tight as to cause either undue tension or strangulation of the contained tissue.

The effectiveness of this method in preventing post-operative hernia through Hesselbach's triangle—so called "recurrence"—is such that fascial grafts, darns with silk or nylon, filigrees, and the rest can be reserved for exceptional cases. Failures of the method are, I am sure, due to insufficient exposure of the pubic spine and consequent inadequate placing of the first and all-important stitch—I am, etc.,

Edgware, Middlesex

FRANK FORTY

### Penicillin in the Treatment of Neurosyphilis

SIR—Will you allow me to add a postscript to your leading article on penicillin in the treatment of syphilis (July 17, p 141) or rather to that paragraph of it which deals with neurosyphilis? Our American colleagues have a larger number of cases to treat than we have in this country, and it seems most likely that the question whether malarial therapy will still be necessary in G.P.I. and allied conditions will be settled by their experience, and their reports are now coming forward so rapidly that our few British accounts are superseded by the time they are published.

In a recent paper by Stokes<sup>1</sup> and his colleagues entitled "Three Years of Penicillin Alone in Neurosyphilis," observations on 321 cases are summarized. These authors continue to take the view (which I am unable to share) that the immediate

clinical improvement with penicillin in cases of paresis is not as great as that with malaria, but among their conclusions are the following:

"Malaria in paresis is superior to penicillin alone in the clinical improvement produced when compared with the first year or two of penicillin responses, but penicillin rapidly overtakes malaria in the second and equals it in the third year of observation. Taking the durability of penicillin effect, the comparative simplicity, short duration, and safety of penicillin therapy into account, it begins to look as if penicillin alone were the equal of malaria in paresis. Spinal fluid results are apparently superior with penicillin to those obtained with malaria.

"In tabo paresis the fluid improvement with penicillin definitely surpasses that obtained with malaria, and the symptomatic improvement with penicillin is equal after the second year in meningo-vascular neurosyphilis; the results are markedly superior serologically and equal clinically."

Dathner<sup>2</sup> has recently summarized his observations on 151 patients treated with penicillin alone. Among these were 33 cases of general paresis and 19 cases of tabo-paresis, and they are considered chiefly in relation to the spinal fluid results. In two cases of general paresis the results were regarded as indefinite, but in all the others they were satisfactory in that the spinal fluid syndrome indicated an arrest of the disease process. Dathner is more clear than some other observers that all that can be expected from treatment is the extermination of the infection, and that symptomatic improvement thereafter depends on the recovery of the nervous tissue—a process which we have as yet little power to influence—I am, etc.,

### Prevention of Venereal Disease

SIR—There will be no quarrel with the aim of the National Society for the Prevention of Venereal Disease, which in Lord Horder's words (July 17, p 171), is "to set the people free from V.D.", but there is no such general agreement as his letter implies, even among the experts, about the methods by which it is likely to be attained. Many would contest his assertion that in the protection of the fighting Services during the war the enthusiasm of the officer-in-charge" (for preventive measures) was the decisive factor where such "protection" was achieved. Indeed, some medical officers having pressed prophylactic measures by every means at their disposal were driven to the conclusion that by so doing they had not diminished but increased the rate of infection in their units. "Enthusiasm" in this context is inseparable from the assumption that promiscuous sexual behaviour will be the general rule. That assumption, especially when openly avowed by the M.O., is bound to lower the resistance to such behaviour, among young soldiers in particular, and therefore leads to a higher exposure rate.

A good deal of wartime experience indicates that the amount of disease prevented by the "enthusiastic" advocacy of prophylaxis was balanced (some would say was outweighed) by the amount of infection among those who, without the prophylactic policy and its powerful suggestion, would not have incurred the risk of it. To retort that most Service men are promiscuous and that therefore all should be protected is precisely to beg the question, for even if the assertion be true it cannot be known how far the assumption by those in authority that the Service man's promiscuity is simply a fact to be reckoned with and, so to say, provided for is a major cause of the problem. No one should be too dogmatic upon this point. But Lord Horder and those who think with him should give due weight to the results in a number of units of different assumptions about the men's standards and conduct and of the "combined operations" of C.O.s, M.O.s, and men who tackled the problem in a more constructive and, I think, to affirm a more enlightened way.

Lord Horder speaks of the "violent prejudice" which a society has to combat. It may be that all the prejudice is on one side, and that those who insist that V.D. must be viewed as a medical problem and no more are leaving out of account factors which, however imponderable, are in the end decisive. V.D. is not just a medical or even a social problem, it is

*penicillin  
nonad tulle*

The efficacy of the local application of penicillin has been established by its use in the forms of powders, solutions, creams, and ointments. A new development is the introduction of Penicillin Nonad Tulle. This non-adherent sterilized gauze dressing of wide mesh is impregnated with an emulsifying base of soft paraffin and anhydrous lanoline, containing 1,000 units of penicillin per gram equivalent to 160 units per square inch of Tulle.

Submitted for trial in hospital practice, including special branches of surgery, Penicillin Nonad Tulle has been welcomed as a dressing for infected wounds and burns and for operation wounds, including those of eyes, ears, and nose, and those of skin grafting.

ROBERT FORGAN

G. L. RUSSELL

SIR—In the *Journal* of July 17 (p. 171) Lord Horder writes on this important subject. There is no real proof that chemicals in prevent infection. It is probable but not certain that they may be effective under carefully selected experimental conditions but in view of the known speed with which syphilis becomes spread from the point of implantation, and the obvious difficulties of use under the conditions of sexual exposure their use in practice is another matter. Condoms protect a limited area and again, for reasons not difficult to deduce, they are feeble defences.

In actual fact I have had extensive experience of organized prophylaxis in the Royal Navy, the Army, and to a less extent in relation to a very large civilian clinic. My considered opinion is that these measures are futile. As a venereologist I did not find they had protected my patients, nor did they appear to affect the volume of my work. Indeed, I am certain from discussions with thousands of persons of various social and intellectual levels that the sense of false security encouraged by taking of risks. Chemicals may also prevent the appearance of local lesions although the individual actually acquires the disease; such persons spread infection as symptomless carriers and may later suffer the grave results of untreated, unsuspected infection.

Even in the Services, where self-treatment was an offence and medical advice was readily accessible, prophylactic materials were used for self-treatment and this is even more likely in civil life. The degree of protection given by a limited rubber envelope plus chemicals is not one which I would regard as adequate for my hands if exposed to infective discharges in examining a patient. For the genitals, in the more prolonged and intimate contact of coitus they are even less reliable.

For those who nevertheless wish to experiment on themselves condoms are on sale and also mercurial and silver preparations, and I am therefore at a loss to know what action Lord Horder wishes the State to take. I am certain from my own practical experience that those who do so experiment will in time discover that there is no reliable prophylaxis for venereal infections—I am etc.

ROBERT FORGAN

R. C. WEBSTER

SIR—It is a matter for regret that Lord Horder has suggested July 17 (p. 171) that V.D. is on the increase, when the fact is that in England the number of cases of fresh infection reporting at V.D. centres is again declining. Not that the actual figures give cause for complacency but the trend is in the right direction, as was to be expected when the effects of demobilization began to subside and infections from the army of occupation were more effectively dealt with.

The Trevelin Committee (1922) whose report shared the usual fate of being entirely ignored by the Government, made no suggestions that might have been adopted with advantage. The first quoted by Lord Horder was that "properly and promptly applied disinfection would almost certainly prove effective" and the National Society for the Prevention of Venereal Disease maintains that V.D. is on the increase (which it is not) because the facts of disinfection have been withheld from the civilian population. The second suggestion of the Committee was that for an experimental period in a limited area measures of compulsion were worth trying.

It may do little harm if Lord Horder and his followers proclaim from the house tops the virtues of urination after coitus with soap and water, potassium permanganate solution and calomel cream. But is this message of hope really worthy of the extravagant language of his letter? A great campaign to set the people free. The scope and magnitude of this great attack depends upon the support we receive from the profession. Are we really to talk to the cry of "Permanganate and calomel" or are we not rather soberly and sadly to reflect that in England today V.D. clinic officers and M.O.H.s have no legal powers to prevent persons known to be infected from spreading gonorrhoea and syphilis or to bring under treatment the husband of a wife he has infected, the parents of infected children and the brothers and sisters of young congenital syphilitics?

On balance it might not be to the disadvantage of the public health that the sale should be legalized of preventive materials with instructions for their use although sometimes these would be used to treat early symptoms. But the danger arising from the renewed activity of the NSPVD is that the public may be misled into imagining that nothing more is needed to eliminate V.D.—I am, etc.

Brentwood Essex

ROBERT FORGAN

SIR—Space permits only a brief and dogmatic reply to Lord Horder's letter (July 17, p. 171), but the following points merit consideration.

1 The only sure preventive of V.D. is chaste living by both men and women outside marriage and fidelity within marriage.

2 Any propaganda which obscures this fact is likely to increase promiscuity and hence to increase the opportunity for the dissemination of V.D.

3 Propaganda of the kind advocated by Lord Horder is of this nature. It can only interest personally those who choose to lead a promiscuous or illicit sexual life, but the weak and the unprincipled, especially among the young will be influenced by it.

4 A degree of safety through such scientific chemical methods is of course possible to men and women who are prepared to take immediate steps regarding self-disinfection with every act of illicit sexual intercourse, and to become adepts at "mournful medical immorality." Even if used with the utmost care, however, preventives are not 100% safe. Without such care they merely give a false sense of security.

5 Persons who want knowledge of and access to such preventives can obtain them if they make sufficient effort. There is no need to make the practice of immorality easy or to encourage the waverers.

6 The armed Forces have for many years had easy access to prophylactic packets, are instructed in their use and often encouraged to use them. Yet the incidence of V.D. in the armed Forces is always one of the greatest worries of the authorities—I am, etc.

K. B. HARDWICK

General Secretary  
The Association for Moral and Social Hygiene

London SW 1

SIR—I believe that the great majority of those who have had practical experience of the problems associated with venereal disease will disagree very strongly with the ideas put forward by Lord Horder (July 17, p. 171). The first part of his letter seems to imply that in some ways the Ministry of Health is to blame for an increase in venereal diseases in 1945.

Now I am sure that the Ministry needs no defence from me but I think that in common fairness it should be stated that at least the results of the provisions for the diagnosis and treatment of V.D. by the Ministry in the past have been very good indeed, even though there is room for improvement.

Lord Horder says that the "alarming setback has dismayed everyone." Surely everyone who knew anything about venereal disease or its history expected a "setback." Has there ever been a war that did not produce an increase in venereal disease? The only surprise to most informed observers was that the setback was delayed.

A necessary inquiry, which has a very considerable bearing on the propaganda suggested by Lord Horder, is as to the reason for the setback. I would suggest that it arises to a not inconsiderable extent by the use of the very methods advocated in his letter. For have not the troops in Germany and elsewhere been given this type of education, which tells them that V.D. can be easily prevented and are not these same troops very largely responsible for the spread of venereal disease in our civil population to-day, particularly to their wives? We are told that the V.D. incidence among the troops in Germany was 185 per 1,000 for 1947. What an advertisement for prophylaxis!

Lord Horder goes on to say that a great deal of V.D. can be easily prevented. What is meant by "easily prevented" is a matter of opinion but in any case the crux of the matter lies in a later statement that "properly and promptly applied disinfection would almost certainly prove effective." Does

Lord Horder think for one moment that a person without any medical knowledge could or would apply an antiseptic "properly or promptly"?

In reply to the threefold policy I would say that it is not a scientific fact that V D can be easily prevented, that to "supply interested persons" with details of preventive measures without proper safeguards seems to me to be the best possible method of promoting the spread of venereal disease and immorality, and that to allow the indiscriminate advertisement and sale of these preventive materials must inevitably encourage immorality—I am, etc.,

Birmingham

E W ASSINDER

### National Hearing-aid

SIR,—A headband is as inconvenient to a man as it is to a woman who needs some aid for hearing, and the disadvantages of easily detached parts are only too evident among travellers and country residents, so that in Natal one commonly encounters deafened persons who have purchased expensive aids but have been forced to discard them. A short trial of an instrument is of little avail, for a small mechanical defect is likely to occur at any time unless the attachments are fool-proof, and devices which prove suitable close by, as in a store, are of little avail when seeking to discern speech at a distance. Unfortunately international trade still keeps the price in South Africa to approximately £35 for one instrument in spite of favourable notices about most of the makes by the National Council for the Deaf's widely circulated magazine—I am, etc.,

Durban

F GORDON CAWSTON

### Training of Nurses

SIR—Dr J H Weir's letter (July 10, p 109) confirms the opinion of many members of the profession that the standard of "medical" learning required of nurses is unnecessarily high. Like Dr Weir I attempt to infuse into groups of exhausted, young women the details of clinical medicine expected by their curriculum.

Unlike the ward and out-patient work of the medical student, their daily labours, comprising practical nursing, have little in common with "academic" medicine. Doctors with experience in general practice know that a high percentage of women who have had no training can provide excellent nursing after very little tuition. Experience during the war showed that men could provide the same. At a time when the nursing profession is so short of members it seems absurd to continue the high standard of the past. In the medical profession doctors are graded by examination and experience into general practitioners and specialists. I see every reason why a similar practice should be adopted in the nursing profession—I am, etc.,

Chester

PHILIP R GRAVES

### Administration of Medicine

SIR—May I, as one who had the privilege of serving with him in the C M F, be permitted to make some comments on the first of the two Croonian Lectures delivered by Dr E R Boland in November, 1947, and reproduced in an abridged form in the *Journal* of July 3 (p 9)? Although it is indeed a pleasure to read an article, lecture, or other communication by an ex-temporary member of the medical branch of one of our fighting Services which is not filled with carping and too often destructive criticism of the Service concerned, certain points raised and statements made by the lecturer appear to require elucidation or even correction in fairness to the authorities concerned.

**Medical Planning.**—In the first place one notes with relief that Dr Boland avoids the all too frequent and usually unfair comparison between our medical services and those of our American friends and allies. It is indeed true, and how often did one hear it said, that the Americans (to use one of their own expressions) "got things done", thus they certainly did and usually in a far shorter time than we were or had been accustomed to. But it should be remembered that to obtain this rapid and no doubt effective result they were most uneconomical both in man power and material, this being the inevitable result of the immense resources of both available to them, especially in the field of "transportation" by land, sea, and air.

**Standardization of Treatment.**—Apart from the reasons in favour given in the lecture, it should, I think, be stressed that this was bound up to a great extent also with the availability or shortage of some drugs and items of medical equipment. How often does one recall impassioned appeals from hospital divisional officers or specialists for some drug, dressing, or item of special equipment for use in some "special" case or series of cases? Frequently the item in question was either not available or was in short supply, nor in point of fact was it really necessary in a standardized and general medical service. In no case, so far as my personal experience went, was there ever any but a very temporary shortage of any essential item, at least in the C M F.

**Suggested Improvements.**—1 Higher Administration. Desirable though it may appear that the medical services should be divorced from control by the Adjutant-General, it should be realized that such a "revolution," and revolution it would be, cuts right across a long-established practice in respect of other administrative services and also that of the sister fighting services both British and Allied. In many ways we in the British Army were far better placed in this respect than those in the Royal Navy, Royal Air Force, or the American Army, in none of which could the medical services be said to hold any "executive" authority. Though it may be true, as Dr Boland puts it, that "recommendations and observations have to pass through intermediaries who have the power of suppressing or altering them," in point of fact it was seldom if ever that any alteration or suppression was made, and direct access by the director, if not to the commander-in-chief at any rate to the chief administrative officer and/or the chief of staff, was always available. In the C M F all heads of services attended both C O's and C A O's conferences and were asked their opinions in any relevant discussion at such *directly* and not through the chief staff officer of the adjutant or quartermaster general.

2 Professional Status and Promotion. Here again one cannot but agree with the lecturer in principle, but at the same time some of his statements are not strictly accurate. It is true that in war promotion to higher rank has up to now been far easier to attain on the "administrative" as compared with the "professional" side. No reference however, is made in the lecture to the many professional improvements instituted as a result of the Warren Fisher Committee recommendations some years before the last war. Since the time of this committee officers of high professional attainment have had far more than the four senior appointments quoted by Dr Boland to aim at, I need only mention officers i/c hospital divisions (who had in the large majority of cases been specialists for some time before the war), professors and assistant professors at the R A M College, deputy or assistant directors of hygiene and pathology, O C school of hygiene, command consultants, etc.

**Stores and Equipment Branch.**—The following points should, I feel, be stressed in fairness to the small but devoted and efficient cadre of quartermasters who organized and administered base and other medical stores. (1) Supply. This was largely, as indeed it had been before the war, under "civilian" control, at any rate at the source. Shortages were world wide in certain commodities, especially those obtained from Eastern sources, and although large reserves had been built up in peacetime these could not be expected to compare with those of the Americans with their greater resources and shorter "carry". (2) Distribution. From home to overseas bases immense difficulties did occur, largely if not wholly due to shortage of shipping space or enemy action, but from bases to forward areas, at any rate in the C M F, distribution never failed, and forward shortages, if they ever occurred, were rare (subject to my comments under "Standardization"). (3) Accounting. The method finally evolved in the C M F could hardly be described as "archaic," and it was certainly not "lacking in system." As far as base depots were concerned it should be realized that estimates had to be calculated six months or more in advance in overseas theatres owing to the long "carries," and that the "turn over" was enormous owing partly to the practically unrestricted use of drugs and dressings and also to the necessity of avoiding deterioration in many commodities. That the system was efficient is I think proved by the fact that the C M F Base Depot, containing at the time some 4,000 tons of stores of a value of over £1,500,000, was eventually closed down and the contents disposed of with infinitesimal losses and without the prolonged courts of inquiry necessitated in the case of some other administrative services.

—I am, etc.,

Pulborough Sussex

G P KIDD

### 'The Homosexual in the Courts'

SIR—While Dr Eric Coplans' letter (July 3, p 53) is certainly timely, it seems only fair to impute to legal and public opinion the primary responsibility for the retention of our archaic laws on homosexuality, and to absolve from blame in respect psychiatrists and sociologists who have for many years fought to overcome the "conspiracy of silence" and ignorance.

Indeed ever since the latter part of the nineteenth century eminent medical men seeking to shed the light of science on purification of curiunism have clearly advocated a more rational attitude on the part of the law and society. Krafft-Ebing<sup>1</sup> stated that the punishment of homosexuality *per se* does not deter from crime and has no corrective influence for pathological manifestations are not removed by penal remedies. Decidedly it is not an atonement for a criminal act which can only under certain and mostly false presumptions be considered as criminal and thus may lead to acts of gross injustice. The writings of Havelock Ellis, Raffalovich,<sup>2</sup> Moll,<sup>3</sup> Stekel, and above all Hirschfeld<sup>4</sup> detailed and forthright discussion of the whole question must also be mentioned. Clifford Allen has ably criticized the still prevalent legal misconception that sexual perversion is "the result of wicked impulses capable of being checked by advice and resolution."

A clear and constructive sociological analysis of this problem has recently been made by H. Mannheim<sup>5</sup> who states that the fact that the inverts' sexual activities which he is often unable to regard as abnormal are treated as serious crimes by the law is likely to make him profoundly anti-social and produce the mentality of an outlaw. Alexander and Staub<sup>6</sup> concluded that the solution of the problem is not the punishment of the adult, but the proper management of the child. The revengeful attitude of society towards the victims of its own mistakes is cruel, useless, and purposeless. Ruth Benedict<sup>7</sup> has well stated the effect on the homosexual of social and legal condemnation. "His guilt, his sense of inadequacy, his failures, are consequences of the disrepute which social tradition visits upon him, and few people can achieve a satisfactory life unsupported by the standards of their society. The adjustments that society demands of them would strain any man's vitality, and the consequences of this conflict we identify with their homosexuality."

It must be stressed that contemporary English law on this question as embodied in the Offences against the Person Act 1861 and the Criminal Law Amendment Act 1885, is derived from Exodus xxii 19 and Leviticus xxi 17-20 and xx 13-16. There is no reference to female homosexuality in either. These Old Testament laws may or may not have conformed to the ethical and social needs of the Jewish Kingdom about 625 B.C. but they can have little place in our western civilization of the twentieth century A.D. Discussing the evolution of the attitude of Christianity to homosexuality, Weir Marchant<sup>8</sup> says:

To be called wrong in a yet must be productive of other harm than the mere inversion it causes, provided that the agent has not in an indecent manner shocked any one's feelings. Any moral condemnation of homosexual practices (nobody can, of course, be blamed on account of his abnormal desire) must be founded on an opinion of their harmfulness individual or public, whatever they may be. But thoughtful people will be on their guard against the common tendency to seek a rational justification for judgments springing merely from sentimental dislikes.

The very least that could be hoped for then would be the modification of English law on homosexual offences to bring it more into line with that on heterosexual offences as is the case in the French *Code Pénal* (art. 330 ff.), and the rational treatment of those who have committed anti-social sexual acts. For the words of Isaac Ray<sup>9</sup> on the legal concepts of insanity are in this instance also as true to-day as they were over a century ago:

It is to be feared that the principles laid down on this subject by legal authorities have received too much of that reverence which is naturally felt for the opinions of our ancestors and that innovations have been too much regarded rather as the offspring of new-fangled theories than of the steady advancement of medical science. The ministers of the law seem to have forgotten that the real dignity and respectability of their profession is better upheld by their fully receiving the truth from whatever quarter it may come than by turning away with blind obstinacy from everything that conflicts with long-established maxims and decisions."

—I am, etc.

## Obituary

G. W. GOODHART M.D. F.R.C.P.

Dr. G. W. Goodhart died at his home in London on July 16 after an illness from which he had suffered many attacks during the last five years. His courage in this time was an inspiration to all who knew him. He had almost reached his 66th birthday and he retired only last year from his post as pathologist of the group laboratory at St. Mary Abbots Hospital in the London County Council's Public Health Department.

Gordon Wilkinson Goodhart was the younger son of Sir James Goodhart Bart., of Guy's Hospital. He was educated at Westminster School, Trinity College, Cambridge and Guy's Hospital, and graduated M.B. in 1908. At his teaching hospital he became house physician, Gull research student, Douglas demonstrator in pathology, and senior assistant bacteriologist. Subsequently he worked in Germany in Aschoff's department at Freiburg and in Berlin. His next principal appointment was that of clinical pathologist at University College Hospital. During the war of 1914-18 Dr. Goodhart was in France with the R.A.M.C., acting as pathologist to the 2nd London General Hospital. After the war he resumed his work at University College Hospital and over the next thirteen years developed his considerable and very individual talents as a clinical pathologist. During this time he gave his assistance to physicians and surgeons, taught students and junior colleagues, and did research work with Charles Bolton and Preece Jones.

In 1931 Dr. Goodhart was appointed one of the pathologists in the hospital services of the London County Council first at Archway Hospital and after 1933 at St. Mary Abbots Hospital, Kensington. He gave skilled service to patients and colleagues in a way that placed medical work in its proper perspective among the duties and satisfactions of human fellowship. His work in different committees was most helpful because by his good judgment he convinced others. It was typical of him that an address which he once gave on the significance of leucocytosis was the result of years of experience and gave a surprisingly illuminating view of a well-worn subject. He was president at different times of the Association of Clinical Pathologists of the Medical Society of London and of the Section of Pathology of the Royal Society of Medicine. He married in 1914, Alice Stransham La Touche and they had two daughters and a son.

Dr. Janet Vaughan writes: "England has produced not a few physicians, surgeons and pathologists of international repute in the last thirty years. Gordon Goodhart who died in London last week was probably not known outside this country and yet he made possibly as great a contribution to English medicine in those years as his better-known contemporaries. He carried out at one time a considerable amount of original work, particularly in association with Charles Bolton on problems of gastric secretion but his greatness lay in his power of synthesizing the science of the laboratory with the art of the physician—a synthesis which he achieved quite unconsciously. By his own example he taught a long succession of students at University College Hospital and many colleagues in the medical service of the London County Council that work in the laboratory cannot be divorced from work at the bedside. What he saw down the microscope in the test tube, or in the post-mortem room only became real to him in relation to the individual sick man, woman or child, whom he had always to see with his own eyes—it was not enough to hear a case report. It is easy to say that Gordon Goodhart was one of the first men in this country to teach and practise clinical pathology as we know it to-day. It is true but it does not give the full measure of his quality which was compounded not only of knowledge but also of wisdom and experience and of judgment perhaps inherited in part from his father. Gordon Goodhart was indeed a beloved physician. He was also the most trusted friend, unfailing in his help and understanding of personal problems. During the years of the war he was often ill but he carried on his hospital literally blitzed to rubble round him, with a gay courage that will never be forgotten by those of us who were

lucky enough to work in the same part of London and inevitably turned to him for help in elucidating the new problems that war brought to medicine and to individuals. Many men and women to-day would say that Gordon Goodhart taught them what has really mattered in their medicine. They would also like to say how much they loved him.

Dr Joan Taylor writes. Clinical pathologists throughout the United Kingdom will mourn the death of Dr G W Goodhart. Clinicians and students alike were always welcomed to his laboratory with a courtliness rarely encountered in these modern times. His mellow voice, ready smile, and kindness made many of us seek him out whenever possible, as we knew that apart from his friendly advice we should not go away without some addition to our knowledge of pathology. He was at his best when discussing a problem in the wards, giving details of laboratory investigations and correlating these with the clinical findings. Such discussions frequently merged into reminiscences of similar or related conditions which he had encountered, these were most amusing and of the utmost educational value. I well remember him collaborating with the late Dr Charles Bolton on changes in the test-meal found in various intestinal conditions. These two white-haired benevolent gentlemen would retire to the laboratory, where they would get through much experimental work and in addition discuss the life and progress of the hospital in all its detail. Those of us who had the advantage of being his assistants know that our fundamental outlook and attraction towards clinical pathology were engendered by him. He was beloved by all who knew him and was the outstanding example of the fact that the good clinical pathologist is not only a laboratory worker but a physician with a profound knowledge of the art of his subject.

Dr J E McCartney writes. On behalf of the group pathologists of the London County Council Pathological Service I should like to pay tribute to our great friend and colleague the late Dr Gordon W Goodhart. He came to the service at its inception in 1931, and his mature experience and wise counsel assisted greatly in its rapid development. He was appointed first to the Group Laboratory at the Archway Hospital, and when he had organized this he then developed the laboratory at St Mary Abbots Hospital. Goodhart was much liked and respected by all his colleagues and staff, and his help and advice, particularly in haematology, were ever forthcoming. His absence through illness was a great loss to us, and his death now robs us of one whom we held in affection and esteem.

#### SIR HENRY SYMONS, KBE, CSI

Major-General Sir Thomas Henry Symons died on July 3 at Church Crookham, Hampshire, following an accident. He was 76 and had been Director-General of the Indian Medical Service for the four years preceding his retirement in 1930.

Thomas Henry Symons was born at Falmouth in 1872. He was a student at Charing Cross Hospital and qualified in 1894. After acting as house-physician and resident obstetric officer at Charing Cross Hospital he successfully competed for the IMS in 1896. He had five years on the military side before being posted to Madras in charge of the general hospital there. Later he was a district civil surgeon until the outbreak of the first world war, when he was given command of the hospital ship *Madras*. In 1923 he was appointed surgeon-general to the Madras Government, an appointment which he held for three years. Then in 1926, when Sir Charles MacWatt retired, he succeeded him as Director-General of the IMS and continued in that capacity until his own retirement in 1930. Sir Henry Symons was president of the South Indian and Madras Branch of the British Medical Association from 1923-6, and in the following year he presided over the Congress of the Far Eastern Association of Tropical Medicine. He was created KBE in 1929.

P H writes. During the past few weeks we have lost some of the veterans of the Indian Medical Service. "Jullundur" Smith, John Lunham, "P P" Kilkelly and "T H" Symons were well known throughout India. But how many of their fellow-countrymen at home noted their passing? The late General Sir Ian Hamilton has told us in one of his best books that the

British people dislike versatility. All these four men were surgeons, Smith and Kilkelly ophthalmic surgeons, Lunham and Symons general surgeons. But the claims of Kilkelly, Lunham, and Symons to niches in the temple of fame do not rest upon surgical skill. They will be remembered rather as Kilkelly the dashing cavalryman, Lunham the polo player, and Symons the master of hounds. The Indian Medical Service has provided many masters for Indian packs of hounds, and shall we say, *primus inter pares* General Sir Henry Symons, Director General of the Service, master of the Madras and Delhi hounds, and well known in the Ooty country, where he rode many winners of point-to-point races. The Indian Medical Service, like the Bengal Lancer, has gone with the wind. But those of us who had the honour to belong to that grand corps may perhaps be forgiven for casting a wistful glance back to those days of colour and panache when Irvine and Symons hunted hounds and showed us such sport.

#### ALEXANDER BALDIE, MB, DPM

Dr Alexander Baldie died at St Lawrence, Isle of Wight, on June 23 at the age of 62. He was born in Cape Colony, South Africa, but received his medical education at Edinburgh and the London Hospital, qualifying MB, BCh in 1912. Throughout the first world war he served in the RAMC, and in 1917 was awarded the French Médaille d'Assistance Publique. He next held the appointment of DCMs under the Ministry of Pensions in Southern Ireland during the very 'troubled' period 1920-3. It was shortly after his return to England that he became deeply interested in psychological medicine and particularly psychotherapy and the problems of delinquency. He was one of the first honorary psychotherapists to be appointed to the West End Hospital for Nervous Diseases, and he continued his association with that hospital, where his admirable work was always greatly appreciated, for the rest of his career. He also took the diploma of psychological medicine in 1934 and became a member of the staff of the Institute for the Scientific Treatment of Delinquency.

Dr Baldie's outstanding and most valuable work however was performed during the long period that he acted as surgeon to the important C, D, and E divisions of the Metropolitan police area. These divisions include the West End of London and contain the well known stations of Bow Street and Vine Street. Of Dr Baldie it may be truly said that he was a pioneer in introducing the psychological aspect of delinquency to magistrates' courts and pointing out that in many instances the offence was the result of psychological abnormality rather than of deliberate criminal intent. Dr Baldie was thus instrumental in changing the attitude of many judicial authorities and in numerous cases he was able to secure that young offenders were sent to appropriate schools and that adult delinquents were referred for suitable treatment. Further, on account of his scrupulous fairness and sound judgment he enjoyed the confidence of the judges and magistrates before whom he gave evidence. By the police force he was held in the highest esteem and his opinions were invariably accepted. The work of such an important police area, however, was very arduous and exacting. Dr Baldie was not the man to spare himself and there is no doubt that overwork contributed to his final illness. He developed hyperpæsis, and early in 1944 had his first attack of cerebral thrombosis. Nevertheless, as soon as he had recovered from the more disabling effects of the malady he insisted on resuming much of his work, until a second attack in 1945 compelled him to retire.

Dr Baldie was always a keen member of the British Medical Association, and was chairman of the Kensington Division in 1936 and the Marylebone Division in 1943-4. He also served on the Dominions Committee for four years. Of quiet and unassuming personality, he was an indefatigable worker and a staunch friend. Although he made some valuable contributions to medical literature, particularly on the diagnosis of intoxication with alcohol and drugs and on "alcohol and the motorist" it is to be regretted that his exacting and practical duties prevented his writing more extensively on his unique experience in medico-legal matters and the psychological problems of delinquency. Dr Baldie's remains were cremated and the ashes scattered over the sea facing his charming house at St Lawrence.—E W-D

## D A WELSH MD FRCPd

Dr D A Welsh a graduate of Edinburgh University who became Emeritus Professor of Pathology at the University of Sydney, died on May 13 at Wahroonga, Australia at the age of 82.

David Arthur Welsh was born in Forfarshire, Scotland. He graduated MB, ChB with first-class honours in 1893, proceeded MD four years later, and was elected FRCPd in 1911. He was lecturer in pathological bacteriology and senior assistant to the professor of pathology at Edinburgh University for some years. Then in 1902 he went to Sydney to take up the newly created chair in pathology there. He acted as honorary pathologist to the Royal Prince Alfred Hospital until 1925 and is honorary consultant pathologist until 1936. When a radium clinic was opened in Sydney in 1928 Professor Welsh with a number of collaborators including his son Dr Arthur Welsh began a study of the radio sensitivity and radio resistance of cancer cells which was to continue for the rest of his professional life. In 1935 the Senate of the University of Sydney formally recorded its appreciation of the services he had rendered to the University over the previous thirty years and appointed him Professor Emeritus.

Professor Welsh wrote his MD thesis on the parathyroid glands and from that time onwards he contributed a number of important papers to the literature on this subject and on diseases of the blood. He also did valuable work on snake poisoning, hydrid disease, tuberculosis and, particularly in the last ten years of his tenure of the chair of pathology on cancer. A complete bibliography and a very full appreciation by Professor Keith Inglis appear in the July 3 issue of the *Medical Journal of Australia*.

## F McG LOUGHNANE FRCS

W P G writes. The death of Mr Farquhar McGillivray Loughnane (July 24 p. 229) has come as a sad blow to his many friends. Concerning his outstanding professional achievements and contributions others are better fitted to speak but the writer can look back on a long period of pleasant and fruitful professional association which commenced in 1933, when he was appointed as consultant urologist to the Bethnal Green Hospital. As a cystoscopist and intravesical instrumentalist he was seen at his best, the speed and precision with which he could remove a prostate with the resectoscope was a revelation of what could be done in this direction. Of a reserved disposition, Loughnane was not easily known, but once his confidence had been gained he proved to be a delightful friend and most agreeable colleague. To patients and members of the nursing staff he extended an old world courtesy which was pleasant to observe. Remembering perhaps his own early struggles he was kindness itself to junior members of the staff. It was always the junior member of the team who passed the cystoscope for him and he went to great pains to demonstrate cystoscopic appearances to junior nurses. In his young days he had been a keen golfer but towards the end he got caught up in these most enthralling of hobbies—restoration of old country cottages and gardening. He liked in his spare moments to steal away to his home on the Kentish coast and there to mingle with the country folk and fishermen. We who knew him well revere his memory and our deepest sympathy is extended to Mrs Loughnane.

Dr PERCY EDWARDS died at the home of his younger son Dr C. K. D. Edwards in Ainsdale, Southport, on June 14 after a very brief illness at the age of 84. He was the son of James Latchford Edwards and was born in Rochester. He was educated at Mill Hill and University College London qualifying in 1886. After a period as house-surgeon at the Western General Dispensary in London he was appointed medical superintendent at Sheffield Fever Hospital and later resident consultant medical officer at Monsall Fever Hospital, Manchester. Dr Edwards made several trips to America and Africa in the capacity of ship surgeon before he began general practice in Newton Park, Liverpool in 1894. He remained there until he retired in 1927. He was honorary medical officer to the Liverpool Seamen's Orphanage for more than thirty years. Dr Edwards had been a member of the British Medical Association since 1888 and served as honorary secretary of the Liverpool Division from 1915 to 1921. He was a representative at the Annual Representative Meeting held at Portsmouth

in 1923 and was elected chairman of the Liverpool Division for 1923-4. During the 1914-18 war he served on the Central Medical War Committee in London and for his services was awarded the OBE. Since boyhood he had been keenly interested in entomology and he possessed a particularly fine collection of British moths and butterflies all of which had been collected or bred, by himself. This collection he eventually presented to the Liverpool Museum. He married in 1894 Eleanor Blanche the younger daughter of Henry Smith of Dartmouth who predeceased him. He leaves two sons—Dr F. H. Edwards of Shrewsbury and Dr C. K. D. Edwards of Ainsdale, Southport.

Mr Hugh Reid writes. Dr Percy Edwards was a man who never failed his patients however arduous the task before him. In those much more difficult days of medical practice before the first world war when the facilities of hospital and laboratory organization were relatively primitive he could tackle with confident efficiency whatever emergencies came his way. Neither obstetrical alarms nor industrial accidents nor the complicated problems of medical practice dismayed him, for he had studied and worked and prepared for them. His relations with his medical colleagues approached the ideal for he expected the best from them. Whether in the many committees of the B.M.A. where he devoted so much of his time and skill or in the more direct contact with his fellow practitioners his sage counsel was unstintingly given. His more intimate friends remember especially his profound knowledge of English history, his fascinating collection of entomological specimens, and his justifiable pride in the two sons whom he leaves to carry on the ideals and the traditions of which he was the true example.

Dr ALBERT JONES, who had been medical officer of health and school medical officer for Widnes for the past thirty five years, died suddenly at his home on June 17 at the age of 62. Dr Jones was born in Liverpool and educated at Wallasey Grammar School and Liverpool University, where he graduated MB, ChB in 1902. He took the DPH two years later and proceeded MD in 1913. Dr Jones was in practice in Ormskirk for about two years and was then on the staff of the Lancashire County Council before being appointed as the first full-time medical officer of health and school medical officer for Widnes. He did a great deal of valuable work in the town in connexion with maternity and child welfare. Dr Jones joined the R.A.M.C. early in 1915 and quickly rose to the rank of lieutenant-colonel with command of a field ambulance. He was awarded the MC in 1917 and the DSO in 1918. Towards the end of his service he was D.A.D.M.S. of a division in France. Dr Jones was an Officer Brother of the Order of St John of Jerusalem, and during the recent war, in addition to his ordinary duties, he was largely responsible for creating the ARP services in his area. Dr Jones leaves a widow and four sons, three of whom are doctors.

Dr CHARLES WILLIAM WINDSOR died in a nursing home at Royston on June 22 at the age of 77. Dr Windsor was educated at Magdalene School, Brickley, at Cambridge, and at St Thomas's Hospital. He graduated MB, BCh in 1894 and proceeded MD three years later. Early in 1898 he joined the partnership of Balding and Archer in Royston and there he continued in general practice until 1941. During the 1914-18 war Dr Windsor served with the R.A.M.C. and was with No. 55 General Hospital in France until 1919. He was a member of the Royston Urban District Council for over twelve years and was at one time chairman of the council. He was also a justice of the peace for the county and a well-known churchman. Dr Windsor had been an invalid since his retirement and the sympathy of all who knew him will be extended to his widow and two sons, one of whom is in practice at Walton on Thames.

## The Services

Wing Commander (acting Group Captain) C. A. Rumball OBE, RAF, has been appointed Honorary Physician to the King.

Air Commodore E. D. D. Dickson, CBE, RAF, has been appointed Honorary Surgeon to the King.

Major-General W. E. Tyndall CB, CBE, MC, late R.A.M.C., has been appointed Honorary Surgeon to the King and Major-General J. J. Magner CB, MC, and Brigadier H. T. Findley, late R.A.M.C., have been appointed Honorary Physicians to the King in succession to Major-Generals E. A. Sutton CB, CBE, MC, and Sir Trevelyan O. Thompson KCSI, CB, CBE, and Lieutenant-General Sir Alexander Hood, GBE, KCB, KHP, late R.A.M.C., retired, respectively.

## UNIVERSITY OF BRISTOL

The following candidates have been approved at the examinations indicated

MD—G. H. Wattleby  
FINAL MB ChB—Barbara Brosnan Suzanne K. R. Clarke R. S. G. Davies C. C. Downie M. J. Dunn Molly I. Govier, Pamela I. Hannaford A. H. Levy (with distinction in forensic medicine) Jenny Pym F. A. A. Ruggen, B. F. Vaughan, G. Wintermuzz R. H. Wood In Group II (completing examination) Elizabeth H. Chard In Group II only G. D. Teague, A. S. Wallace In Group I only Pamela L. C. Watson  
D. Ph.—Part II R. G. Brennan J. B. M. Davies D. M. M. Jones E. W. Moore W. Nicol  
DIPLOMA IN PSYCHOLOGICAL MEDICINE—Part II W. L. Jones R. Maggs J. R. Stuart  
DIPLOMA IN RADIOTHERAPY—Part II A. A. G. Flemming F. A. Hanna

## ROYAL COLLEGE OF SURGEONS OF ENGLAND

On July 1 Sir Harry Platt was re-elected and Mr. R. C. Brock and Sir Archibald McIndoe were elected members of the Council of the College. The result of the poll was as follows

Sir Harry Platt (Royal Infirmary, Manchester)	672
Sir Archibald Hector McIndoe (St. Bartholomew's Hospital)	454
Russell Claude Brock (Guy's Hospital)	418

The following were the other candidates	
Arthur Dickson Wright (St. Mary's Hospital)	416
Rodney Honor Maingot (Royal Free Hospital)	353
Eric William Riches (Middlesex Hospital)	331
Angus Hedley Whyte (Royal Victoria Hospital, Newcastle-upon-Tyne)	266
Alan Cecil Perry (London Hospital)	239
Harold William Rodgers (Royal Victoria Hospital, Belfast)	217
Hugh James McCurrich (Royal Sussex County Hospital, Brighton)	206
Ronald Henry Ottywell Betham Robinson (St. Thomas's Hospital)	205
Hubert Wallace Symons (General Infirmary at Leeds)	178
Marriott Fawcner Nicholls (St. George's Hospital)	149
Alexander Croydon Palmer (King's College Hospital)	132

In all 1,588 Fellows voted, in addition 22 votes were found to be invalid

## ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

At a quarterly meeting of the College held on July 20, with the President, Dr. W. D. D. Small, in the chair, Dr. D. R. Maitland (Edinburgh) and Dr. E. K. Morris (Edinburgh) were introduced and took their seats as Fellows of the College. Dr. J. Laurie (Dumfries) and Dr. W. M. Wilson (Edinburgh) were elected Fellows of the College.

Drs. D. R. MacCalman (Aberdeen), J. G. A. Davel (Pretoria), H. D. Jenner (Prince Albert, Saskatchewan, Canada), J. Sandilands (Iron Aston, Gloucester), I. C. Gilliland (London) E. M. Donaldson (Edinburgh), P. W. Hannay (Edinburgh), V. V. Shah (Bombay), J. Green (Glasgow), J. S. Theron (Bloemfontein), R. W. Biagi (Bangour, W. Lothian), D. I. McCallum (Edinburgh), T. Parkin (Sheffield), A. R. Wilson (Edinburgh), A. A. C. Ross (Milton Bridge, Midlothian), Amy Jungalwalla (Bombay), D. M. Forsyth (Edinburgh), N. C. Begg (London), D. S. Harling (Edinburgh), R. G. Mathers (Wallasey) E. V. B. Morton (Edinburgh), J. K. Scott (Bangour, W. Lothian), J. A. Tulloch (Forres, Morayshire), D. Naidoo (Busby, Lanark), J. A. Morton (Edinburgh), D. Banerji (Calcutta), T. W. G. Kinnear (Edinburgh), A. M. Kassim (Bombay), C. F. Rolland (Edinburgh), A. C. Arthur (Edinburgh), and H. D. Ritchken (Johannesburg) were elected Members of the College.

## Medical Notes in Parliament

## NATIONAL HEALTH SERVICE

MR BEVAN announced on July 20 that as an interim measure he had approved the continued use for doctors' private patients of any hospital accommodation so used immediately before the appointed day until regional boards could review the position and draw up considered proposals. The hospital management committee concerned was responsible for the admission arrangements. Hospital charges would be determined by the committee in accordance with the National Health Service (Paybed Accommodation in Hospitals, etc.) Regulations (Supplement p. 61), which also prescribed maximum fees recoverable by the medical practitioner for professional services. Receipts from hospital charges would be paid into the Exchequer.

## Prescriptions for Private Patients

SIR ERNEST GRAHAM LITTLE asked on July 20 why the patients of doctors who remained outside the National Health Service were debarred from receiving free medicine although eligible for free treatment?

MR BEVAN answered that the diagnosis, the prescription, and its provision must be treated as part of one process. He could not justify separating the prescription as Sir Ernest suggested.

## Rural Practitioners and Special Hardships

MAJOR TUFTON BEAMISH on July 22 asked if the Minister of Health was aware that, owing to the fact that no travelling allowances were paid to doctors for visiting patients in their homes, doctors in rural districts were obliged to refuse registrations from persons living more than a short distance from their surgeries. He asked Mr. Bevan to take steps to prevent the health of the rural community suffering in this way.

MR BEVAN said special payments, details of which are under discussion with the British Medical Association, would be made to meet such cases. He added that there was no financial justification for a doctor refusing a patient in the circumstances described.

DR SANTO JEGFR said many doctors who had joined the National Health Service were in serious financial difficulties because their income from private patients had largely ceased. Their panel cheques paid early this quarter had been exhausted by their regular commitments, and they had no current money to meet day-to-day expenses. He asked Mr. Bevan to arrange for doctors to receive interim payments, on account of their basic salary or otherwise, to bridge the interval until their next regular payments became due.

MR BEVAN did not think there could be many such cases but proposed to arrange for advances to be made in cases of special hardship.

Replying to Mr. CHETWYND, MR BEVAN stated that the provisional figure of the number of general practitioners who had joined the Service in England and Wales by July 10 was 18,575. The figure was subject to further checking. He added that the total number of general practitioners in England and Wales (including assistants who would not normally be included in the medical list) was believed to be about 21,500.

## Streptomycin

MR SWINGLER raised on July 21 the subject of the supply of streptomycin to hospitals. He gave details of a case a week earlier in which a doctor in the Staffordshire Infirmary applied urgently to the Ministry of Health for streptomycin for treatment of a young girl suffering from tuberculous meningitis. He was refused a supply on the ground that the Staffordshire Infirmary was not a hospital authorized to have a supply. He was told that the patient must be sent to the nearest authorized hospital, which was the Queen Elizabeth Hospital in Birmingham. There he was told that although there was a supply of streptomycin there were no vacant beds. Mr. Swingler said an appeal was made to him for assistance and he was told that application must be made to the Emergency Bed Service, which would allot a bed in a hospital where there was a treatment unit employing streptomycin. The Emergency Bed Service in London had no immediate vacancies in any of the hospitals which had streptomycin. Yet at the same time the Ministry of Health issued a statement saying that the supply of streptomycin was now fairly satisfactory. The upshot of the case was that the supply of streptomycin in Staffordshire Infirmary was authorized by the Minister of Health. Mr. Swingler

asked about the position of the manufacture of streptomycin in the United Kingdom and how soon the nation would be independent of supplies from the U.S.A. How many more hospitals did the Minister expect to be authorized to have a supply and a treatment unit when the regional boards had made their plans? If there were not sufficient beds in these hospitals who had discretionary power to send a supply to other hospitals?

MR BEVAN said it was undesirable that where a time-lag developed between the discovery of a drug and its use throughout the whole health system there should be sensational propaganda alleging that people were dying because it was not available and at the same time raising false hopes and fears in the breasts of those concerned about individual cases. He hoped the British press would not sensationalize incidents so as to cause a feverish atmosphere when what was required was calm and judicial investigation. The use of streptomycin was still in its early stages and it should be administered under hospital conditions and preferably with laboratory controls. The Medical Research Council had established that some cases of tuberculous meningitis did react favourably to the use of streptomycin. In about 31% of the cases hopeful results had been realized—which showed that it was still ineffective in the majority of cases. Restriction of the therapeutic use of streptomycin in Great Britain was inevitable until the Ministry had satisfied itself that its clinical use was safe. It had now been established that it was to some extent efficacious both for tuberculous meningitis and military tuberculosis. Arrangements were being made to provide treatment for as many such cases as possible. Similar arrangements would apply if streptomycin was reliably shown to be of value in other cases. A supply was being planned and British production increased to meet these needs. All regional boards had been asked to say at what hospitals or sanatoria these cases could be brought together. To economize the skilled services of the doctors concerned it was desirable to group these cases, 26 such treatment centres had been provided. As soon as the location of additional ones was known supplies of streptomycin would be provided for them. In other hospitals arrangements had been made to supply streptomycin for cases if there was no bed for them in a recognized centre. A doctor at any hospital could get streptomycin for such cases by applying to the Ministry of Health's Supplies Division, whose telephone number was Kensington 3471, Extension 102.

From July 14 to July 19, 1,150 g of streptomycin had been supplied in response to twenty-five requests of this kind. Clinical trials now suggested that cases of tracheobronchial tuberculosis should be brought within the treatment scheme. Regional hospital boards had been asked to say which hospitals should receive supplies of streptomycin for this purpose. An expert medical committee was being set up to advise what other types of case, in the light of clinical trials, should be brought within the scheme. Arrangements would be extended on the basis of that advice. In order to treat all cases of military tuberculosis, tuberculous meningitis, and tracheobronchial tuberculosis in the country, not more than 40 kg of streptomycin would be needed every month. From November, 1946, to August, 1948, 309 kg of streptomycin would have been imported from the United States at a cost of £777,000. A further 50 kg were on order. Large-scale production of streptomycin in this country was beginning. It was expected that 25 kg would be packed, tested, and ready for issue this month and at least 50 kg in August. By the autumn, production should reach 100 kg a month. Plant with much larger capacity should come into operation early next year. If the extent of the therapeutic use of streptomycin was not increased before the end of the year we should be in a position to meet all domestic needs and to export some streptomycin, but domestic claims must come first. Mr Bevan pointed out that the Ministry of Health was not administratively responsible for this matter until July 5. He contended that it had carried out with considerable speed the reorganization of hospitals concerned with the use of the drug.

### Food Inspection

In a statement on July 21 Mr STRACHEY announced that under the Transfer of Functions (Food and Drugs) Order, 1948 which came into operation on March 1, and the Public Health (Amendment) Regulations, which came into operation on June 1 the Ministry of Food had taken over from the Ministry of Health the central responsibility for food inspection and food hygiene generally. He intended to seek the co-operation of local authorities and their officers, the food trade, and the public in a concerted effort to combat the dangers to health which result from the preparation, storage, or handling of food in unclean or otherwise unsatisfactory conditions. Shortage of essential equipment and of building labour and

materials hampered immediate improvements. However, existing legislation could be made more effective by the voluntary adoption of codes of practice applicable to particular trades, and by stimulating among all concerned a more positive attitude to food hygiene. In these matters the Ministry of Food would work in close consultation with the Ministry of Health, which remained responsible for measures for dealing with infected food and food poisoning, and with the local authorities concerned with the enforcement of the relevant provisions of the Food and Drugs Act, 1938, and of the regulations made thereunder.

*Dentists in N.H.S.*—Answering Mr Sharp on July 20, Mr BEVAN estimated that about 10,000 dentists were in general practice in England and Wales. By July 10, 5,386 had joined the Service, an increase of 824 in five days.

*Scottish Chemists*—Replying on July 13 to Mr NIALL MACPHERSON Mr WOODBURN announced that he had reached an understanding with the representatives of the Scottish chemists on July 1, and that the chemists had been providing pharmaceutical services under the new National Health Service scheme since July 5.

*Medical Students*—According to the latest information there are 9,671 full time medical students at universities in England and Wales, and 2,840 are directly State aided. In addition, an unknown number hold local education authority major awards.

## Medical News

### Princess Alice Emergency Hostel for Mothers and Babies

The National Children Adoption Association (71, Knightsbridge, London, S.W. 1) has converted "Castlebar," Sydenham Hill, London, S.E., previously the Princess Alice Nursery Training College, into an ante- and post natal hostel, now known as the Princess Alice Emergency Hostel for Mothers and Babies. Up to forty mothers can be admitted, twenty ante- and twenty post-natal cases, and there is a nominal weekly charge. Antenatal cases are accepted by arrangement, but the expectant mother, however, may not be admitted less than two weeks before the expected birth of the child. Post-natal cases are accepted upon the discharge of the mother and baby from hospital, and mothers may remain up to three months with their infants if they so desire. Alternatively, should a mother wish to have her baby adopted the association would make the necessary arrangements. The mothers are left entirely free to decide the future of their children.

### Central Council for Health Education

The Central Council for Health Education held its twenty-first Annual General Meeting and Council Meeting on July 22. Lord Woolton was reappointed President, and the Vice-Presidents of the Central Council, Sir Allen Daley and Dr Charles Hill, were re-elected. Mr Henry Lesser retired from the chairmanship and was succeeded by Dr E. K. Macdonald, the Medical Officer of Health for the City of Leicester. Dr W. A. Bullough, County Medical Officer of Health, Essex, was elected Vice-Chairman. Sir Graham Savage, who had served as Honorary Treasurer for four years, retired from that office and was succeeded by Dr Robert Forgan. Mr Henry Lesser said that from September onwards the Council would provide two day courses in health education free of charge every two or three months at over a dozen universities in England, Wales, and Northern Ireland. The lecturers would include several outstanding authorities whose daily duties gave them many opportunities for health education.

### Sir Max Page

Sir Max Page has been appointed an officer of the Legion of Honour by the French Government.

### Lyttel Lily Cup

Dr A. M. Amsler has been awarded the Lyttel Lily Cup of the Royal Horticultural Society. Dr Amsler was medical officer at Eton College for thirty years.

### Streptomycin

The Ministry of Health points out that under the arrangements for supplying streptomycin for cases of military tuberculosis and tuberculous meningitis applications by telephone should be made as follows: 8.30 a.m. to 6 p.m., Monday to Friday, and 8.30 a.m. to 2 p.m. Saturday—Kensington 3471, Extension 102, all other times (night and week-ends), Whitehall 4300. In the recent debate in the House of Commons on streptomycin only the Kensington telephone number was mentioned.

# INTRAVENOUS ANAESTHESIA

with

## 'KEMITHAL' SODIUM

'Kemithal' Sodium (sodium cyclohexenyl-allyl-thiobarbiturate) is a new ultra-short-acting intravenous anaesthetic, evolved in the ICI Research Laboratories

In extensive clinical trials, 'Kemithal' Sodium has proved to be a highly efficient and satisfactory agent for basal hypnosis and for surgical anaesthesia of short or prolonged duration

Having a relatively high therapeutic quotient, 'Kemithal' Sodium effects anaesthesia without undue respiratory depression. A number of workers have commented upon the reduced incidence of laryngeal spasm with 'Kemithal' Sodium

Literature on request

'Kemithal' Sodium is issued in ampoules of 1 gramme and 2 grammes in boxes of 5 and 25, with or without sterile distilled water in ampoules of 10 c.c. and 20 c.c. respectively, ampoules of 5 grammes 'Kemithal' Sodium are also available in boxes of 5

### Case History

GHH Aged 38 Dock Labourer Injured his left shin whilst at work. On attending the clinic he had a deep traumatic ulcer surrounded by an inflamed area of skin no varicose veins (Fig 1)

**Treatment.** August 9th, 1946—Jelonet was applied to cover the ulcer and inflamed area, and a pad of cotton-wool to cover the ulcer only. The leg was bandaged from toes to knee with Viscopaste (Fig 2)

August 23rd, 1946—The inflamed area was re-dressed with Jelonet covered by strips of Ichthopaste. A well-bevelled adhesive sponge rubber pad was applied to cover the ulcer, and the leg firmly bandaged with Elastoplast

Sept 13th, 1946—After liberally painting with calamine in oil, covered with Ichthopaste, a large pad of cotton-wool

Fig 2

## TRAUMATIC SHIN ULCER HEALED WITH JELONET, VISCOPASTE, PARAGON SPONGE RUBBER AND ELASTOPLAST

was placed to cover the ulcer and the leg again firmly bandaged with Elastoplast

October 4th 1946—Ulcer healed (Fig 3)

October 18th, 1946—Patient discharged to work

**Comment.** Although initial bandaging with Viscopaste resulted in marked improvement, there was not sufficient pressure as was evident on August 23rd when, although the ulcer was reduced in size, there was pronounced granulation tissue. This resolved rapidly with concentrated compression beneath sponge rubber with the additional support of Elastoplast (August 23rd and September 13th)

Details and illustrations above are of an actual case. T J Smith & Nephew, Ltd, Manufacturers of Jelonet, Viscopaste, Ichthopaste and Elastoplast are privileged to publish this instance, typical of many, in which their products have been used with success, in the belief that such authentic records will be of general interest

**Memorial to the late Professor Noah Morris**

A Morris Memorial Lectureship has been created at Glasgow University in tribute to the memory of the late Professor Noah Morris of the Chair of Materia Medica. Distinguished lecturers in branches of medicine in which Professor Morris was interested will be invited from time to time to address meetings, which will be open to undergraduates, graduates, and the general public. Subscribers to the Memorial Fund include the Students Representative Council, the Student Medical Societies, the Unions, and the Athletic Club, in all of which Professor Morris had taken an enthusiastic interest. Representatives of these bodies and of his medical colleagues and friends met recently, and the cheque representing the contributions to the Memorial Fund was handed over to the University. Mr Marshall Walker in doing so referred to Professor Morris's great gifts as a teacher, his sympathy, moral and intellectual integrity, his enthusiasm and ability to talk, and his knowledge of his subject. He had the gift of winning his students and of transmitting something of his own earnestness and enthusiasm.

**Order of St John for Scotland**

The following members of the medical profession were invested in the Chancery of the Order of St John for Scotland in Glasgow on June 23. As Commander W J Moore, FRFPS, JP (from Officer), as Officers (Brothers), W F J Whitley, MD (from Serving Brother), N G W Davidson, OBE, FRCS, as Serving Brother A A F Peel, DM, FRFPS.

**Rubber Stamps**

The Minister of Health states in a letter to local executive councils that it is legally permissible for a medical practitioner, when signing Form E.C.1, to use a stamped facsimile of his signature or a rubber stamp supported by his written initials. He also suggests that in the present exceptional circumstances—say, up to the end of July—executive councils may accept a stamped form even if it is not a facsimile and not initialed.

**New Journal of Experimental Psychology**

The first number of the *Quarterly Journal of Experimental Psychology* has appeared under the editorship of Mr R C Oldfield, M.A., of the Institute of Experimental Psychology, Oxford University. It is published by Messrs W Heffer and Sons of Cambridge, for the Experimental Psychology Group. The journal will publish chiefly papers on experimental work but will also include others if they advance scientific knowledge. The present number includes a paper on "Traumatic Amnesia," by Dr W Ritchie Russell, and one by Dr N H Mackworth on the Breakdown of Vigilance during Prolonged Visual Search. The subscription is £1 10s a year for four numbers, single copies may be obtained at 8s. Orders should be placed with the publishers.

**Teaching Hospitals at Cambridge**

The Chesterton Hospital at Cambridge has been included in the Cambridge group of teaching hospitals by regulations (SI No 1579) made under the National Health Service Act.

**Wills**

Dr Cyril Strickland of St Helier, Jersey, formerly professor of medical entomology at the Calcutta School of Tropical Medicine and Hygiene, left £20,538. Dr Cyril Henry Hawkins, LDS, of Birmingham, formerly examiner in dental surgery to the Royal College of Surgeons of England, left £20,978. Dr William Wynn-Williams, of Middlesbrough, £49,761. Dr Laurence William Pole, formerly MOH for Llanelly, South Wales £1,169, and Dr Alexander Benham Stutch, of Old Heathfield, Sussex, £19,115.

**COMING EVENTS****International Congress on Population and World Resources**

The Family Planning Association has organized an International Congress on Population and World Resources in Relation to the Family to be held at Cheltenham from Aug 23 to 27 inclusive, when representative delegations will attend from some twenty countries. The subjects to which sessions will be devoted include "World Resources," "Population Trends," "Migration," and "Sociological, Religious, and Political Implications of Contraception in Various Countries," as well as "Current and Future Research into Such Problems." The speakers will include Lord Horder (President of the Congress), Sir John Boyd Orr, Dr Julian Huxley (Unesco), Lady Denman, Mrs Ottesen-Jensen (Sweden), Mrs Margaret Sanger (U.S.A.), Dr C P Blacker, Mr Aleck Bourne, Dr Emde van de Boas (Holland), Mr Kenneth Walker, Prof E Brandstrup (Denmark), Prof T H Davey, Prof David Glass, Prof Joseph Needham, Dr Nils Nielsen (Sweden), Mr Kenneth Rose (U.S.A.), Dr Hugh Sinclair, Dr Abraham Stone (U.S.A.), Dr Durand-Wever (Germany), and Prof Whelpton (U.S.A.). The fee for registration is £2 per delegate, and applications for registration and accommodation should be addressed to the Congress Organizer Mr N A Howell Everson, at 27 Park Street London, W1.

**Medical Historians**

A meeting of the United Kingdom, Dominions and United States Official Medical Historians Liaison Committee will be held at Corpus Christi College, Oxford, from August 3 to 7. The object of this committee which is sponsored by the Governments concerned is to provide opportunities for the medical historians to consult together on technical questions and propose solutions of problems about correlation of data, balance between one official medical history and another, and methods of presentation. The delegates will be the guests of the British Government at a dinner at the Savoy Hotel, London, at the conclusion of the conference. The first meeting of the committee was held in Ottawa in September, 1947, at the invitation of the Canadian Government.

**SOCIETIES AND LECTURES****Friday**

KENT AND CANTERBURY HOSPITAL—At Slater Hall, Canterbury, July 30 7.45 p.m. Clinical meeting. Film on Poliomyelitis, followed by a general discussion.

**Tuesday**

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE—At Anatomy Lecture Theatre, Edinburgh University, August 3, 4.30 p.m. "The Present Position of the Rhesus Factor," by Professor D F Cappell.

**APPOINTMENTS**

PHILPS, A SEYMOUR, FRCS, Surgeon in charge of Eye Department, St Bartholomew's Hospital, London, SE.

Mr Philps qualified at Bart's in 1929 and took the FRCS in 1931. He was formerly Assistant Ophthalmic Surgeon at Bart's.

FAIRMAN H D MB BS, FRCS, Ed DLO Honorary Surgeon to Ear, Nose and Throat Department Bristol Royal Hospital.

HARRISON EIRWEN M MB ChB DPH, Assistant Medical Officer of Health Essex County Council.

## EPIDEMIOLOGICAL NOTES

## Vital Statistics for the June Quarter

Infant mortality in England and Wales for the June quarter of 1948 established a new low record<sup>1</sup>. The rate was 31 per 1 000 live births. The previous lowest rate for any quarter was 32 in the September quarter of 1947. The best previous rate for a June quarter was 39 in 1947. The rates for the six months ended June 30 and for the twelve months ended on that date also establish new low records. The uncorrected rate for the first half of 1948 was 36, the corresponding rate for 1947 was 46, for 1946 it was 45. For the twelve-month period July 1947, to June, 1948 the uncorrected rate was 37, for the twelve-month period July 1946, to June, 1947, it was 42, for the calendar year 1947 it was 41.

The accompanying table of corrected quarterly rates since 1943 indicates that the rates in each of the past four quarters have been lower than the rates recorded for the corresponding quarters in previous years.

## Quarterly Infant Mortality Rates per 1 000 live births in England and Wales from 1943-8

(Corrected for delays in registration of births and for changes in annual births)

Year	1948*	1947*	1946	1945	1944	1943
March quarter	41	55	55	60	58	60
June	31	39	40	41	42	47
Sept	—	32	35	37	40	40
Dec	—	39	43	45	43	50

\* Provisionally corrected (full data for correction not yet available)

The stillbirth rate for the June quarter, 1948, was 23 per 1,000 total births. This is the lowest recorded rate for a June quarter. In the June quarter of 1947 the rate was 24 and in the corresponding quarter of 1946 it was 28. A rate of 23 has previously occurred in the September quarter of 1947. The stillbirth rate for the first six months of 1948 was lower than for any previous year. It was 23.5, compared with 25 for the first six months of 1947 and 28 for the first six months of 1946. The rate for the twelve month period July 1947, to June, 1948 was 23, which may be compared with 26 in the corresponding period from July, 1946, to June, 1947.

The accompanying table of quarterly stillbirth rates shows that, as with infant mortality, the rates in each of the past four quarters are lower than the rates recorded for the corresponding quarters of previous years.

## Quarterly Stillbirth Rates per 1 000 total births (live births and stillbirths) for England and Wales from 1943-8

Year	1948	1947	1946	1945	1944	1943
March quarter	24	26	28	28	29	32
June	23	24	28	27	27	30
Sept	—	23	27	27	27	29
Dec	—	24	27	28	28	30

The number of live births registered during the quarter was 203,711, compared with 202,184 in the previous quarter and 235,174 in the same period last year. The corresponding rates were 19.0, 18.9, and 21.9 respectively.

There were 110,356 deaths registered during the June quarter representing a record low death rate for any June quarter of 103 per 1,000 total population, compared with 11.0 for the second quarter in 1947 and the previous lowest rate for a second quarter of 10.4 in 1945.

In the following table the numbers of live births stillbirths and deaths registered in the June quarter 1948 and the corresponding rates are compared with those for the June quarters 1947 and 1938.

Second Quarter	Live Births		Stillbirths		Deaths		Infant Mortality	
	No	Per 1 000 Total Population	No	Per 1 000 Total Live and Still Births	No	Per 1 000 Total Population	No	Per 1 000 Related Live Births
1938	164 179	16.0	6 639	38.9	119 188	11.6	8,006	50
1947	235 174	21.9	5 831	24.2	118 011	11.0	9 195	39
1948	203 711	19.0	4,733	22.7	110 356	10.3	6 336	31

## Discussion of Table

In *England and Wales* increases were recorded in the notifications of whooping-cough 168, scarlet fever 126, and diphtheria 9. There were decreases in the incidence of measles 150, cerebrospinal fever 18 and dysentery 13.

The largest increases in the incidence of whooping-cough were Lancashire 42 and Surrey 40, the largest decreases were Yorkshire West Riding 41, Yorkshire East Riding 40 and Cheshire 40. The rise in the notifications of scarlet fever was due to a small increase throughout the country, the only local increase of any size was 37 in Lancashire.

The incidence of measles, broadly, showed a slight increase in the Midlands and a fall in the remainder of the country, the largest decreases were Essex 194 and London 95, and the largest rise was Staffordshire 82. No change of any size was reported in the local returns of diphtheria.

An outbreak of dysentery affecting 20 persons was notified from Hertfordshire, Hatfield RD. The largest of the other returns of dysentery was 7 in Lancashire. The only administrative area with more than one case of poliomyelitis was Norfolk Norwich CB 2. The other counties with more than one notification of poliomyelitis were London 3, Dorset 2, Middlesex 2, Essex 2, and Derbyshire 2.

In *Scotland* infectious diseases were less prevalent during the week, and the decreases included scarlet fever 56, measles 37, and acute primary pneumonia 26. A small fall in the incidence of these diseases was recorded throughout the country. An increase in the notifications of cerebrospinal fever from 7 to 12 occurred in the city of Glasgow.

In *Eire* decreases were recorded in the returns of measles 61 and scarlet fever 12, while increases were reported for diarrhoea and enteritis 28, whooping-cough 19, and diphtheria 8. Of the 40 cases of diarrhoea and enteritis 24 were notified in Dublin CB.

In *Northern Ireland* the notifications of scarlet fever rose by 10 while the notifications of measles fell by 12.

## Quarterly Returns for Eire

The birth rate during the first quarter of this year was 21.4 per 1,000 and was the lowest rate recorded in recent years for a March quarter. Infant mortality was 63 per 1,000 births, being 29 below the rate for the first quarter of 1947 and the lowest rate recorded in a first quarter. Maternal mortality was 1.4 per 1,000 registered births. The general death rate was 14.1 per 1,000 and was the lowest rate recorded in a first quarter and 7.3 below the rate for the March quarter of 1947. Deaths from infectious diseases included 104 from diarrhoea and enteritis, 74 from influenza, 52 from whooping-cough, 20 from measles, and 13 from diphtheria. Deaths attributed to pulmonary tuberculosis numbered 692 and, to other forms of tuberculosis 164; these were 112 and 68, respectively, below the average of the five preceding March quarters.

## Scotland's Health in 1947

A report issued by the Department of Health records a birth rate of 22 per 1,000, the highest rate since 1923. A slight rise occurred in infant mortality due mainly to gastro-enteritis. There were 1,123 deaths in the 16 towns attributed to infantile diarrhoea as compared with 642 in 1946. Maternal mortality was 2.0 per 1,000 live births and was the lowest yet recorded. A rise occurred in the incidence and mortality of tuberculosis. There were 10,117 cases and 4,096 deaths from all forms of tuberculosis compared with 9,713 cases and 3,984 deaths in 1946. The 1947 outbreak of poliomyelitis was the largest ever recorded; there were 1,434 confirmed cases, compared with 33 and 41 in 1945 and 1946. During the year 131 deaths were attributed to poliomyelitis.

## Week Ending July 17

The notifications of infectious diseases in *England and Wales* during the week included scarlet fever 1,703, whooping-cough 1,416, diphtheria 183, measles 9,459, acute pneumonia 377, cerebrospinal fever 25, acute poliomyelitis 36, dysentery 67, paratyphoid 12, and typhoid 4.

The Paddington Medical Society has issued its annual report for the year 1947-8. The following officers were elected: president and acting honorary secretary, Dr L. Zeitline, vice-president, Dr S. Brown, treasurer, Dr Z. Green. The following were members of the executive committee: Drs J. Green, H. James, A. Lewis, R. Post, Reece, E. T. Wright, and J. H. Porter. The society held several scientific and clinical meetings during the year, at one of which Dr Dickson Wright introduced a film on "The Treatment of Anaesthetic Conditions and their Complications."

## Any Questions?

*Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.*

## Embalming

**Q**—What is the simplest and most economical method using substances likely to be available anywhere of embalming bodies for preservation during transport elsewhere for burial (e.g. in ships or in tropical countries) when it is necessary to preserve them for a matter of (a) days and (b) weeks?

**A**—From time to time a practitioner is asked to advise regarding the embalming of a dead body, and circumstances may even require that he should carry it out himself. Preservation is attained by permeating the body with a suitable fluid through the vascular system and thereafter injecting a similar fluid into the body cavities and any areas where the penetration of the fluid appears inadequate. It is not essential that the venous system should be drained of fluid blood as a preliminary, but such drainage facilitates penetration of the embalming fluid. Various standard embalming fluids are used, in most of which formalin is the essential ingredient—for example, 20% formalin with 5% borax and 5% glycerin in water. In an average case rather more than 2 gallons (9 litres) of the fluid will be required.

Injectons are made into the arterial system, the arteries selected being the femorals, the brachials, and one of the common carotids. After the arteries and their corresponding veins are exposed, the injections are directed towards the distal extremities of the limbs and, in the case of the common carotid first towards the head and then towards the heart. Penetration is promoted by gentle massage and by flexing and extending the limbs. A satisfactory degree of permeation is indicated by a venous return of the embalming fluid and by a progressive firmness of the part of the body under consideration. The fluid is best introduced into the arteries under pressure through a cannula from a cistern raised about 6 ft (1.8 m). Alternatively, a syringe of the Higginson type may be used but no attempt should be made to force or hasten the injection.

After the arterial injections are completed and after allowing an interval of some hours if possible, further fluid is introduced into the pleural and peritoneal cavities by means of syringe and needle. If there is any aggregation of serous fluid in the pleura, this should first be aspirated, and, similarly, an attempt should be made to remove any fluid or gas from the abdomen. Permeation of the preserving fluid is aided by gentle kneading of the abdomen during and after the injection. Alternatively, the abdomen may be opened and the entire thoracic and abdominal contents removed. They are then washed and placed in alcohol for 24 hours before returning them to the body. In the meantime the cavity walls should be dried as thoroughly as possible. Further injections should then be made into any parts of the body which by their softness indicate an inadequate penetration of fluid. Finally, the entire skin surface, or at all events those parts which will remain exposed, should receive a liberal application of an ointment consisting of 10% thymol in petroleum jelly to prevent the growth of moulds.

There are of course many modifications, some departing slightly, some considerably, from the procedure described. The vascular system may be flushed out by an initial transfusion of saline, for example, and sometimes both carotid arteries are injected instead of only one. A single point of injection, usually into the axillary or femoral artery, may be preferred to the four-point method suggested above, and all the cavity injections, thoracic and abdominal, can be made by means of a long trocar inserted at the umbilicus. Where it is desired to avoid any suggestion of a post-mortem examination the evisceration method will obviously be inapplicable. But the principles are the same in all cases, and the suggested methods, if carefully and thoroughly carried out, will ensure the preservation of the body for very considerable periods even in warm climates. Professional embalmers employ additional means to

provide or procure a pleasant and lifelike colouring and appearance, but even without such additions the results of straightforward methods are often very satisfactory even in these respects

### Haemophilia

**Q**—*A healthy woman who comes of haemophilic stock—two brothers were severely afflicted and died of the disease and there is ample earlier family history—has a healthy little daughter. Is it possible to tell whether the child is a carrier?*

**A**—Haemophilia is due to a recessive gene carried on the X-chromosome. A woman who carries the gene on one of her X-chromosomes is outwardly normal, but will pass on the chromosome with the abnormal gene to half her children on the average. Of the children who receive it the daughters will be outwardly normal carriers like their mother, but the sons will be haemophiliacs, for they possess but one X-chromosome and there is nothing to oppose the action of the abnormal gene. The mother of this woman was a carrier, as is shown by the birth of two haemophilic sons. The chance that she is also a carrier is one in two, and so the chance that her daughter is a carrier is one in four.

An important study by Andreassen carried out during the war (*Opera ex Domo Biologicae Hereditariae Humanae Universitatis Hafniensis* vol 6 Einar Munksgaard, 1943) indicates that the gene may not after all be perfectly recessive, for he was able to demonstrate a delayed coagulation time in carrier women. In his series there was no overlapping, the shortest carrier time exceeding the longest control time by half a minute. Andreassen's work was discussed in a recent annotation (*British Medical Journal* 1948, 1, 697). It is greatly to be hoped that this technique will prove equally successful in the hands of other serologists, and that it will become available in this country. When this happens it should be possible to decide, at least in the great majority of instances, whether women from haemophilic families carry or do not carry the abnormal gene.

### Chronic Lymphatic Leukaemia

**Q**—*What is the latest treatment for chronic lymphatic leukaemia? Are urethane and radioactive preparations of value?*

**A**—Urethane has been used quite widely in the treatment of chronic lymphatic leukaemia with a fair degree of success. The general impression is that this method of treatment is almost as effective as x-ray therapy and is much cheaper. Another advantage is the general availability of the drug. 3–5 g a day may be given until a satisfactory response has been obtained. It should be stopped when the white cell count falls to, say, 40,000 per c mm. Radioactive phosphorus,  $P^{32}$  has been used, about 1–2 millicuries being injected intravenously on the first day and followed by 0.5–1 millicurie at intervals of three or four days, and then, after some four doses have been given, by 0.5–1 millicurie a week until the white cell count falls to, say, 30,000 per c mm. The general opinion is that  $P^{32}$  offers no advantage over deep x-rays as a form of therapy except for those suffering unduly from irradiation sickness. More recently pteroyl triglutamate has been introduced, but no reports of its efficacy are yet available.

### Hypertension and Flying

**Q**—*A woman aged 55 suffering from hypertension (B.P. 250/150) wishes to fly to Canada. Is her hypertension a contraindication to this?*

**A**—Oxygen should be available if this patient flies above 10,000 ft (3,050 m). The hypertension need not preclude her from a transatlantic flight unless there are other complications. The stresses are unlikely to be as great as those of a sea passage when the water is rough.

### Penicillin Inhalation for Bronchiectasis

**Q**—*What strength and volume of penicillin should be used for inhalation therapy in a patient who has advanced bronchiectasis?*

**A**—A usual dose is 100,000 units dissolved in 3 ml of water administered twice daily. A suitable inhaler must produce an extremely fine mist which will penetrate to the lungs, and must be fitted with a face-mask.

## NOTES AND COMMENTS

**Promanide in Leprosy**—Dr GORDON A. RYRIE, Medical Secretary of the British Empire Leprosy Relief Association, writes: "There is a printer's error in the July 24 issue of the *Journal* under the title 'Any Questions' (p. 235). This occurs in the answer regarding 'Promanide in Leprosy'. The dosage is given as '0.3 g daily intravenously'. This should read '3.0 g daily'. In the experience of American workers who have had most experience of this drug the dose can be safely raised to 5 g per day under the same conditions as described in your answer. The treatment of leprosy is fraught with considerable difficulty and may have untoward results in relatively inexperienced hands. In the treatment of any case of leprosy in this country it is probably desirable to seek the advice of the medical consultants of this Association."

**Treatment of Ringworm**—Dr P. M. R. HEMPHILL (Ardglass, Co. Down) writes: "In your answer to the recent question about animal ringworm in farm workers (May 1, p. 865), you never mentioned treatment with the old favourite, Whitfield's ointment, neither did the questioner try this apparently. Recently I have had several cases of this condition in farm workers, some of them severe, with a fierce follicular pustular reaction as you describe, and have achieved rapid healing using Whitfield's ointment spread thickly with a knife on lint strapped over the area, usually the wrist or lower forearm, the dressing being changed daily. This is nothing new, but it may be of some little interest."

**Princess Tsaï Hospital Appeal**—The Princess Tsaï Memorial Hospital in Ethiopia is appealing for a further £20,000 for the purchase of equipment in Britain. Donations will be gratefully received by the Hon. Treasurer, Lord Horder, c/o H. Reynolds and Co., Hon. Accountants, 1, Bloomsbury Court, High Holborn, London, W.C.1.

### Corrections

Dr F. R. Berridge (Cambridge) has asked us to make it clear that the cases he saw in Germany (*Journal* July 17, p. 163) had no evidence of vitamin deficiency. The reference to vitamin deficiencies in the report of his paper, read in the Section of Radiology, concerned changes seen in the small intestine in other states of malnutrition and in patients other than the German series. The reference to "100 g of barium sulphate suspended in 100 ml of normal saline" should have read "150 ml of normal saline."

Dr J. F. Goodwin, Sheffield, writes: "My attention has been drawn to a possible source of confusion to readers in the first table contained in my paper on liver function during thiouracil therapy (July 10, p. 64). The words 'before first test' should be removed from the heading 'Duration of treatment before first test'. The time at which the first test was performed can be ascertained from the column headed 'When first test performed'. Type of abnormality. In addition, Cases 3 and 6 should read 22 months and 10 months respectively 'after stopping treatment' instead of 'after starting treatment'. Case 16 should read 'after 20 months' treatment T.A. positive (4 months before stopping treatment)."

In the annotation on Remuneration of General Practitioners (July 17, p. 143) it is stated in the third paragraph: 'Apart from this central fund, however, there will be an additional amount to be distributed of over £4 million, or approximately £200 per general practitioner in the Service. Furthermore, over and above the capitation fee there will be available to general practitioners income from any one or more of the following sources. The word 'furthermore' should be deleted. The sources from which income will be available to general practitioners in addition to the capitation fee represent in the aggregate a sum of over £4 million. The main sources were listed in the annotation but the list is not exhaustive.'

In our report last week of the meeting of the Section of History of Medicine of the Royal Society of Medicine the last line but one in column two on page 221 should read "Liston's first public operation under ether."

# SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY JULY 31 1948

## PAY-BED ACCOMMODATION

### FEES PAYABLE BY PRIVATE PATIENTS

*The National Health Service (Pay-Bed Accommodation in Hospitals etc.) Regulations 1948 No 1490 were laid before Parliament on July 1 and came into operation on July 5. We print them below.*

The Minister of Health, in exercise of his powers under sections 4 and 5 of the National Health Service Act, 1946 (a), and of all other powers enabling him in that behalf, hereby makes the following regulations:

1 These regulations may be cited as the National Health Service (Pay-Bed Accommodation in Hospitals, etc.) Regulations, 1948, and shall come into operation on the 5th day of July, 1948.

2 (1) In these regulations, unless the context otherwise requires, the following expressions have the respective meanings hereby assigned to them:

'The Act' means the National Health Service Act 1946,  
'The average daily cost per in-patient' means the average daily cost per in-patient of the maintenance of the hospital and the staff thereof and the maintenance and treatment of the in-patients therein,

'Specialist' means a medical practitioner appointed to a hospital for the purpose of practising a special branch of medicine with full responsibility for the treatment of patients or the carrying out of clinical, pathological or ancillary methods of investigation,

'The Minister' means the Minister of Health.

(2) Where any charge authorized to be made by the Minister under these regulations for accommodation or services includes a fraction of a shilling that fraction shall be disregarded if it represents less than sixpence, but otherwise it shall be reckoned as one shilling.

(3) The Interpretation Act, 1889 (b), applies to the interpretation of these regulations as it applies to the interpretation of an Act of Parliament.

### Charges for Accommodation in Single Rooms or Small Wards

3 The charge to be made by the Minister under section 4 of the Act for accommodation in a single room or small ward in a hospital shall be:

(a) for accommodation in a single room, six shillings a day or any part of a day,

(b) for accommodation in a small ward with two or more beds, three shillings a day or any part of a day.

Provided that if in the latest financial year for which information is available the average daily cost per in-patient in the hospital as calculated by the Hospital Management Committee or Board of Governors was less than twenty-four shillings the said charges shall be reduced proportionately.

### Charges for Private Accommodation

4 The charge to be paid under section 5 (1) of the Act in respect of the accommodation and services provided for an in-patient in special accommodation set aside under that section for patients who undertake, or in respect of whom an undertaking is given to pay such charges as are therein mentioned shall be for each day or any part of a day the standard daily charge as determined in accordance with the provisions of the next following regulation, but subject to any deduction which may be required to be made under regulation 6.

5 The standard daily charge for the purpose of regulation 4 shall be determined in manner following:

(1) If the Board of Governors or Hospital Management Committee are in possession of data which enable them to estimate for the current financial year the total cost of the maintenance of the accommodation set aside in a hospital under section 5 (1) of the Act and the maintenance and treatment of the patients treated therein, the standard daily charge to be made in respect of each in-patient shall be determined by reference to the nature of the accommodation occupied by that patient, so however that the total of the standard daily charges fixed in respect of the various types of such accommodation will so far as can be calculated cover in the financial year the total cost above mentioned.

(2) If the Board of Governors or Hospital Management Committee are not in possession of such data, the average daily cost per in-patient during the said financial year at the hospital is estimated by the Board or Committee, increased by twenty-five per centum in case of a single room, fifteen per centum in case of a double bedded room, or five per centum in case of a room containing more than two beds, shall be the standard daily charge.

6 If an in-patient occupying special accommodation set aside under section 5 of the Act makes arrangements under subsection (2) of that section for treatment by a medical practitioner as a private patient there shall be deducted from the standard daily charge—

(1) Where the practitioner is a specialist, an amount representing the average daily cost per in-patient as estimated by the Board of Governors or Hospital Management Committee of the remuneration of the specialists on the staff of the hospital during the financial year, and

(2) Where the practitioner is a general medical practitioner an amount representing the average daily cost per in-patient as estimated by the Board of Governors or Hospital Management Committee of the remuneration of the whole of the medical staff of the hospital during the financial year.

7 The charges to be paid under section 5 (1) of the Act in respect of accommodation and pathological, radiodiagnostic, radiotherapeutic or physiotherapeutic services provided for a patient who makes arrangements under subsection (2) of that section with a specialist for treatment as an out-patient shall in the case of those services described in the First Schedule to these regulations be the charges specified therein.

Provided that, if the Board of Governors or Hospital Management Committee are satisfied on data in their possession that the cost of the accommodation and any radiodiagnostic or radiotherapeutic services is greater or less than the charge so specified, they may make such adjustment of the charge as may be required to secure that it is designed to cover the cost thereof.

### Medical Fees Payable by Private Patients

8 The charges to be made and recovered by a medical practitioner in respect of the treatment of his private patients in pursuance of arrangements made under section 5 (2) of the Act shall not in the case of any treatment described in the Second Schedule to these regulations exceed the charges specified therein or in the case of treatment not so described the charge so specified in respect of the treatment which approximates most nearly to the one in question. Any question arising as to the proper classification of any treatment shall be determined by the Minister.

Provided that if the total of the maximum charges which might under the foregoing provisions of this regulation be made by all the medical practitioners concerned in respect of one series of treatments of a patient for relief of the same

condition exceeds 75 guineas the amount of the maximum charge which may be made for any treatment in that case by any medical practitioner under this regulation shall in the case of each medical practitioner concerned be an amount bearing the same proportion to the appropriate charge specified in the said Schedule as 75 guineas bears to the total of the maximum charges referred to above

Provided also that if the Board of Governors or Hospital Management Committee are satisfied that the patient or some person acting in his behalf has agreed with the practitioner to pay charges in excess of those so specified they may, subject to the provisions of the next following regulation, give notice to the practitioner and the patient or the person acting in his behalf that the limitation on charges imposed by this regulation shall not apply to that case

9 The Board of Governors or Hospital Management Committee shall secure as far as may be reasonably practicable that not more than fifteen per centum of the accommodation made available in a hospital for the purposes of section 5 (2) of the Act is occupied at any one time by patients in respect of whom the limitation on charges has been removed under the last preceding regulation

Provided that if such accommodation comprises less than twenty beds three beds may be so occupied

### FIRST SCHEDULE

#### Hospital Charges to Private Out-patients

1 *Pathology*—(i) For single examinations involving less than 1 hour bench work, 7s 6d, (ii) For multiple and more complicated examinations, 15s

2 *Radiodiagnosis*—Group 1 One extremity, teeth one area foreign body, demonstration of, gall bladder, plain, spine, one area, jaws abdomen, plain, salivary glands, pelvis, chest, without screening, £1

Group 2 Foreign body, localization of all teeth, extremities, several areas, chest, with screening, urinary tract, plain, pregnancy, pelvimetry, cephalometry, mastoid and petrous temporal bones, sinuses, skull, cystography urethrography abdomen screening, cholecystography, cholangiography, fistula, injection of contrast medium, £1 10s

Group 3 Localization of foreign body in eye spine, more than one area, tomography kymography, barium meal, oesophagus, barium meal, stomach and duodenum, barium enema, hysterosalpingography, arthrography, sialography, £2

Group 4 Full barium meal, angiocardiology arteriography, venography, bronchography, ventriculography, encephalography, myelography, £3

3 *Radiotherapy*—For each treatment, 15s

4 *Physiotherapy*—For single treatments, 7s 6d For compound or multiple treatments in one day, 15s

### SECOND SCHEDULE

#### Medical Fees Payable by Private Patients

(a) *In relation to the services of a specialist*

##### 1 Surgeon

(i) Cases involving operation For all services rendered including operation and any necessary attendances and including operations for the implantation of radium or radon seeds—Major operation, 50 guineas Intermediate operation, 25 guineas Minor operation, 10 guineas, provided that if more than one operation is required for relief of the same condition the total fees charged in respect of operations of all classes shall not exceed 75 guineas (For the purpose of this Schedule, 'major,' 'intermediate,' and 'minor' operations are the operations respectively so described in the Third Schedule to these regulations and any other kind of operation which the Minister may from time to time by order classify as falling under one of those headings)

(ii) Cases not involving operation For the first consultation, 5 guineas For the first two days of attendance (including first consultation), 10 guineas For each subsequent day of attendance or consultation, 1 guinea Provided that the above charges shall not together exceed 25 guineas

##### 2 Obstetrician

(i) For booked cases, whether normal or abnormal, including all attendance in the antenatal and post-natal periods, and during labour, and including caesarean section, where necessary, 50 guineas

(ii) Obstetric emergencies, 40 guineas

3 *Physician and any other consultations and attendances not specifically mentioned elsewhere*

For the first consultation, 5 guineas For the first two days of attendance (including first consultation), 10 guineas For each subsequent day of attendance or consultation, 1 guinea Provided that the above charges shall not together exceed 25 guineas

##### 4 Psychiatrist etc

Deep insulin therapy, full course, 75 guineas Modified insulin therapy, electric convulsion treatment, electronarcosis, for each treatment, 3 guineas Special individual psychotherapy, i.e., various analytic methods, narcoanalysis, first consultation or attendance, 5 guineas, subsequent consultations or attendances, 3 guineas each Other cases First consultation or attendance, 5 guineas Subsequent consultations or attendances, 2 guineas

##### 5 Anaesthetist

For each operation, 2 guineas, plus 10% of the surgeon's fee

##### 6 Pathologist

(i) For examination and report Single examinations involving less than 1 hour bench work, 1½ guineas Multiple and more complicated examinations, 3 guineas

(ii) Examinations with clinical consultations, 5 guineas

##### 7 Radiologist

Group 1 One extremity, teeth one area, foreign body, demonstration of, gall-bladder, plain, spine, one area, jaws, abdomen, plain, salivary glands, pelvis, chest, without screening, 2 guineas

Group 2 Foreign body, localization of, all teeth, extremities, several areas, chest, with screening, urinary tract, plain, pregnancy, pelvimetry, cephalometry, mastoid and petrous temporal bones, sinuses, skull, cystography, urethrography, abdomen screening, cholecystography, cholangiography, fistula, injector of contrast medium, 3 guineas

Group 3 Localization of foreign body in eye, spine, more than one area, tomography, kymography, barium meal, oesophagus, barium meal, stomach and duodenum, barium enema, hysterosalpingography, arthrography, sialography, 4 guineas

Group 4 Full barium meal, angiocardiology, arteriography, venography, bronchography, ventriculography, encephalography, myelography, 6 guineas

##### 8 Radiotherapist

For each treatment, 3 guineas, up to a maximum of 25 guineas

9 *Long-stay cases other than psychiatric* 2 guineas a week in addition to any fees payable in respect of surgical operation

(b) *In relation to the services of a medical practitioner other than a specialist*

Any surgical operation including all attendances and other services rendered, 7 guineas For each consultation or day of attendance 15s up to a maximum of 15 guineas

### THIRD SCHEDULE

#### SURGICAL OPERATIONS

##### Major

Abscess of brain	Gastrectomy
Acute appendicitis	Gastro enterostomy
Amputations at hip	Harelip
Amputation of penis (total)	Hernia (strangulated)
Amputations at shoulder	Hydatid of lung or liver
Amputation through thigh	Implantation of radium or radon seeds in the cranium, chest, abdomen, or bladder
Any operation involving intestinal suture	Laminectomy
Biliary fistula	Meningeal haemorrhage
Carcinoma of the colon	Nephrectomy
Cholecystectomy	Perforated ulcer of the alimentary tract
Cholecystenterostomy	Plastic operations requiring tubular graft
Cleft palate or radical operation for malignant growth of palate	Prefrontal leucotomy
Closure of faecal fistula or artificial anus	Prostatectomy
Complete prolapse of rectum involving laparotomy, colostomy, or intestinal anastomosis	Pyelo or nephro lithotomy
Complicated fistula	Radical removal of breast
Cystectomy	Rammstedt's operation
Depressed fracture	Removal of stone from ureter
Diverticulitis	Rupture of bladder
Double inguinal hernia	Rupture of urethra
Drainage of bile ducts	Splenectomy
Epithelioma of the anus	Subphrenic abscess requiring trans thoracic or transperitoneal access
Epithelioma of the tongue with radical operation upon the glands	Sympathectomy
Excision of larger joints	Thyroidectomy for toxic or exophthalmic goitre
Excision of rectum	Transplantation of ureters
	Tumour of the brain

## Intermediate

Abscess of prostate  
Adenoma of thyroid  
Amputation of limbs, save fingers and toes (minor) and thigh, shoulder, and hip (major)  
Amputation of penis (partial)  
Appendicitis (non acute)  
Castration  
Diathermy to growths of tongue or mouth  
Diathermy to growths of bladder (First time intermediate, afterwards minor)  
Drainage of gall bladder  
Empyema  
Enterotomy, colotomy, colostomy  
Epithelioma of lip with excision of glands in submandibular region  
Excision of cysts or tuberculous glands of neck (deep to deep fascia)

## Minor

Abscess  
Amputations of fingers or toes  
Any condition treated by surgical diathermy under general anaesthesia, other than mouth, or tongue or bladder  
Aspiration of cerebral cyst  
Blood transfusion (Grouping and expenses of donor extra)  
Cystoscopy  
Dilatation of anus for fissure  
Dilatation of rectal stricture  
Dilatation of urethra  
Division of fibrous anus  
Examination under anaesthetic  
Hydrocele (injection)  
Implantation of radium or radon seeds for treatment of a skin tumour  
Injection of Gasserian ganglion

## GYNAECOLOGICAL OPERATIONS

## Major

*Vulvo-Vaginal*  
Anterior and posterior colporrhaphy  
Any vaginal operation when combined with coeliotomy, viz., colpopernicoplasty with ventrofixation  
Radical excision of vulva and glands

*Uterus and Adnexa*  
Repair of vaginal fistulae  
Cyst of the broad ligament  
Hysterectomy  
Salpingectomy (acute inflammation, complicated pyo- or hydro salpinx, extrauterine gestation)

## Intermediate

*Vulvo-Vaginal*  
Colpopernicoplasty  
Colporrhaphy  
Perineorrhaphy

*Uterus and Adnexa*  
Dilatation with intrauterine operations  
Evacuation of retained products

Simple myomectomy  
Simple ovariectomy  
Simple salpingectomy or salpingostomy (chronic)  
Simple ventrofixations  
Simple ventrosuspension

*Cervix*  
Trachelorrhaphy and amputation

## Minor

*Vulvo-Vaginal*  
Circumcision  
Clitoris, prolapsus urethrae  
Colpomy  
Cysts or simple tumours  
Relief of atresia vaginae  
Removal of caruncle

*Uterus and Adnexa*  
Induction of radiation menopause  
Curettagé

*Cervix*  
Biopsy of endometrium  
Dilatation  
Insufflation  
Removal of polyp

## EAR, NOSE, AND THROAT OPERATIONS

## Major

All operative treatment of malignant disease  
Bronchoscopy (operative)  
Excision of larynx  
Excision of upper jaw  
External operations on the sinuses and radical operations for tumours of sinuses  
Intracranial complications such as cerebellar abscess

Laryngo fissure  
Ligature of jugular vein and opening of lateral sinus  
Oesophagoscopy (operative)  
Pharyngotomy  
Plastic operations requiring a tube graft  
Radical mastoidectomy

## Intermediate

Diagnostic bronchoscopy  
Diagnostic oesophagoscopy  
Intranasal operations  
Laryngoscopy (operative)

Removal of tonsils by dissection without use of guillotine (18 years and over)  
Simple mastoidectomy  
Simple tracheotomy

## Minor

Diagnostic laryngoscopy  
Guillotine removal of tonsils (18 years and over)  
Opening of quinsies  
Opening of retropharyngeal abscesses

Paracentesis  
Plastic operations not requiring a tube graft  
Reduction of deformity, fractured noses, and facial bones  
Simple removal of facial polyp

## OPHTHALMIC OPERATIONS

## Major

Corneal grafting  
Detachment of retina  
Exenteration of orbit  
Extraction of senile cataract  
Glaucoma, acute or chronic  
Iridectomy  
Kronlein's operation

Operation for dislocated lens  
Ptosis  
Reconstruction of eyelids  
Removal of intraocular foreign body  
Removal of intraorbital tumours  
Strabismus

## Intermediate

Conical cornea  
Corneal abscission or tattooing  
Corneal wound  
Epicanthus  
Excision of lacrimal sac, all methods  
Excision of rodent ulcer  
Excision or evisceration of eyeball  
Exploration of orbit

Lacrimal abscess  
Needling capsule after senile cataract  
Needling juvenile cataract  
Orbital abscess  
Paracentesis  
Radon applications for neoplasm  
Trichiasis

## Minor

Canaliculus and lacrimal duct exploration  
Cauterization of corneal ulcer  
Chalazion  
Ectropion  
Entropion

Excision of pterygium  
Peritomy  
Removal of dermoid  
Removal of foreign body embedded in cornea  
Suturing lid wounds

## ORTHOPAEDIC OPERATIONS

## Major

Amputation through thigh  
Congenital club-foot  
Congenital dislocation of the hip  
Disarticulation of the hip and shoulder  
Excision of cervical rib  
Excision of larger joints  
Internal derangement of the knee and other joints  
Laminectomy  
Open reduction of fractures  
Operative treatment of compound fractures  
Radical operations for bone tumours  
Reconstructive operations on bones and joints  
arthrodesis  
arthroplasty  
bone grafts

Repair of intricate tendon injuries  
Secondary nerve sutures  
Severe congenital and acquired deformities requiring open correction  
Spina bifida  
Tendon transplantation  
Other orthopaedic operations requiring an equivalent degree of surgical skill

*Note*—Charges for the above operations to include the immediate mechanical after-treatment and subsequent changing of splints and plasters (with or without anaesthesia)

**Intermediate**

Amputation of limbs, save fingers and toes (minor) and thigh, shoulder, and hip (major)	Manipulation of larger joints
Closed reduction and fixation of fractures involving joints or shafts of larger bones	Open correction of simpler deformities
Emergency operations for acute osteomyelitis and acute suppurative arthritis	Hallux valgus
Excision of bursae communicating with larger joints	Hallux rigidus
	Pes cavus
	Torticollis
	Primary nerve and tendon repairs
	Other orthopaedic operations requiring an equivalent degree of surgical skill

**Minor**

Amputation of toes and fingers	Manipulation of smaller joints
Application of plaster-of-Paris casts with or without anaesthesia	Removal of exostoses
Hammer toe	Removal of small bursae
	Simple manipulation or tenotomy and plasters

## TRANSFER AND COMPENSATION REGULATIONS

The National Health Service (Transfer of Officers and Compensation) Regulations, 1948, which the Minister of Health has made under Section 68 of the National Health Service Act, 1946, and which have been issued with Ministry of Health Circular 124/48 of July 3, will concern whole-time medical and lay officers of public health or hospital staffs who on July 5 were transferred from the service of a local authority to that of a local health authority or from municipal or voluntary hospital service to that of the regional hospital boards. They concern also whole-time officers of hospitals, insurance committees, and other bodies which now become part of the National Health Service, or those who gave part of their whole time to hospitals which are now transferred or for functions which ceased or were transferred on the appointed day. The regulations do not, however, concern part-time officers—for instance, general practitioners who gave part-time service to local authorities for welfare clinic work, vaccination or immunization, and so on.

**Transfer**

Regulation 6, which lays down eligibility for transfer from a local authority to a local health authority, is quite clear in its effect on departmental medical officers of the metropolitan and non-county boroughs or county districts which have hitherto been welfare authorities, but is not so clear in its application to the medical officers of health of such minor authorities. The wording is

"All officers who immediately before the appointed day were employed by the Common Council of the City of London, the council of a metropolitan borough or the council of a county district solely or mainly for the purposes of functions transferred from that council on consequence of the Act to a local health authority shall on that day be transferred to and become officers of that authority."

There may clearly be some uncertainty arising from the word 'mainly' in the case of an M.O.H. much of whose time has hitherto been devoted to administrative and clinical work in maternity and child welfare. The only criterion of the proportions of his various duties may be the allocation of his salary by percentages to public health, maternity and child welfare, school health duties, and perhaps an infectious diseases hospital. As the Society of Medical Officers of Health has pointed out to the Ministry, these percentages are not a very reliable guide, since they have often been arbitrarily fixed according to the policy of the local authority in grant matters. Indeed, it could appear that, if more than 50% of his salary had been allocated to a function transferable under the Act, the M.O.H. would be automatically transferred to the service of the local health authority in whose county area his borough or district was. This is clearly not the intention, and the Society

suggested to the Ministry that, whatever the proportional allocation of his salary, an M.O.H. should be regarded primarily as an M.O.H., the statutory office in which he has security of tenure. In practice it is believed that some county councils have proposed to their boroughs or districts that the services of their M.O.H. should be lent to the county for maternity and child welfare or other Part III functions on a repayment basis. This procedure will leave the M.O.H. concerned as officers of the borough or district in the same way as borough S.M.O.s in "excepted districts" for school health service purposes. It will also, however, preclude the M.O.H. from entering the new National Health Service superannuation scheme. If, on the other hand, he is definitely appointed as divisional or assistant county M.O. for more than half of his time, he would appear to be eligible under Regulation 39 (3) of the Superannuation Regulations to enter the new scheme if he so wishes.

All appeals regarding transfer as distinct from questions of eligibility for and the assessment of compensation should be made to the Minister (Regulation 9).

**Grounds for Compensation**

Regulation 10 provides that every existing officer (eight years' service is the qualifying period) "who suffers loss of employment or diminution of emoluments which is attributable to the passing of the Act shall be entitled to have his case considered for the receipt of compensation under these regulations" (to be determined in accordance with provisions of the Schedule).

The above general statement is subject to the following conditions set out in Regulation 11

"Nothing in the last preceding regulation shall entitle a person to have his case considered for compensation unless

(a) the cause of the claim to compensation arises not later than ten years after the appointed day, and the claim is made not later than two years after the date on which the cause of claim arises, and

(b) (i) his office is abolished and he is not offered a reasonably comparable office in the Government service or the local government service or under any body constituted under the Act, or (ii) his appointment is determined because his services are not required or because his duties are diminished (no misconduct being established), or (iii) his emoluments are diminished

Provided that for the purposes of this regulation a person shall not be deemed to have been offered an office which is not reasonably comparable with an office which is abolished by reason only of the fact that the duties of the office offered are duties in relation to the administration of a different service from that in connexion with which his office was held or the duties which involve a transfer of his employment from one place to another within England or Wales."

Debatable points are likely to be the interpretation of the words "reasonably comparable office" in (b) (i) and the first alternative in the proviso, that the offer of duties in the administration of a different service shall not be deemed unreasonable and therefore a ground for compensation. It may be assumed that a senior assistant medical officer who has been engaged in the administration of a non-county borough's maternity and child welfare service might have a claim for compensation if he or she were assigned to purely clinical duties in the county council's maternity and child welfare service, but would not have a claim if he or she were given administrative duties in the county's school health service. The second alternative in the proviso, in the case of a public health medical officer transferred from a non-county borough or district to the county council in whose area he works, means only that it is not a ground for compensation if he is moved to duties in a different part of the county. In the case of a hospital medical officer he would have no claim against transfer to any other part of England and Wales, but this is not a very likely contingency.

**Procedure and Assessment of Compensation**

An officer who decides that he has a claim for compensation will have to make it in a form approved by the Minister and deliver it to the compensation authority, which is defined as follows

(a) where the claim is by an officer of a county or county borough council or by an officer of a local authority who suffers through the transfer of functions to the local health authority, the county or county borough council,

(b) where the officer suffers by the cesser (coming to an end) of any function of his authority, that authority

(c) where the officer is employed by a committee or joint board which is dissolved by section 78 (1) of the N.H.S. Act the local authority which appointed the committee or one of the constituent authorities of the joint board

(d) in any other case (e.g. a medical officer in a hospital or in the tube culosis or V.D. services which are transferred to the regional hospital board), the Minister

Any dispute as to which is the compensating authority will be determined by the Minister, or if he is a party to the dispute by the Treasury

The compensating authority have to consider any claim forth with and notify the claimant within one month from the receipt of the claim if they are not satisfied that he is eligible under Regulations 10 and 11. They must likewise notify the claimant within three months of their decision and assessment of compensation if he is considered eligible. If the claimant is dissatisfied with a refusal to admit the eligibility or with the compensation assessed he may refer the matter to a tribunal appointed by the Minister of Labour in consultation with the Lord Chancellor which may co-opt an assessor with special knowledge or experience on the subject matter.

The first stage of compensation will consist of an interim payment (not exceeding two-thirds of the loss of remuneration) for a period not exceeding three months from the date of claim while suitable alternative employment is being sought and the claim investigated. This interim payment is only payable on loss of employment, not on diminution of emoluments. During this stage the claimant may be required to attend before the compensating authority or the Minister's representative, and may file with him a representative empowered to state his case (Schedule 1 and 2). The interim payment will cease if he finds other employment or if the compensating authority are satisfied that he is not actively seeking employment or has unreasonably refused suitable alternative employment (Schedule 5 (3)).

The second stage if the claim is admitted, will be the annual payment until normal retiring age is reached of one-sixtieth of the net emoluments lost for each completed year of service, plus a further one sixtieth for each completed year since reaching the age of 45 if the claimant is over that age at the date of the loss up to a maximum of two thirds of the emolument lost, but ignoring any other remuneration obtained or offered will be set off against the compensation payment (Schedule 9 (2) Proviso). In assessing compensation the relative security of tenure of the employment lost and of new employment obtained has to be taken into account.

Within two years after the decision is notified by the compensating authority or the tribunal the former may review their decision or that of the tribunal and increase or decrease the compensation in the light of any material change in the case. The claimant also has a right to require a review within the same period and to refer the decision to the tribunal if he is dissatisfied. If at any time the officer obtains employment remunerated from public funds the amount received will be counted against his compensation payment, and he has to notify the compensating authority (Schedule 37 and 38). Successful claimants have an option to retain any existing rights as to widows' pensions.

Claims for compensation for diminution of emoluments will be dealt with on lines similar to those for loss of employment but there will be no interim payments and no claim will be admitted where the diminution is less than 5% of the net emoluments of the claimant (net = total remuneration less contributions to the superannuation fund). Compensation payable under this heading will be a proportion of that which would have been payable for loss of office not exceeding the proportion which the sum lost bears to the previous remuneration for the whole employment (Schedule 29).

The third case in the case of a pensionable officer is reached when he attains normal retiring age. The annual compensation payment then lapses and is replaced by (1) an annual payment for life equivalent to the accrued pension rights at the date of the cesser of claim either in respect of the complete loss of office or in respect of the diminution of emoluments with provision for the compensating authority to give added years (up to 25 or such number as he could have normally served which-

ever is the less) if he was over 40 at the date of the cesser of claim (Schedule 20) and (2) a lump-sum retiring allowance if the officer would normally have qualified for this.

For example a medical officer who lost office after 25 years contributory service at age 57 and who fulfilled the requirements of the regulations would receive compensation as follows:

From age 57 to 65 37/60ths of the net emoluments for the lost office (25/60ths for actual years of service plus 12/60ths for year over age 45 at date of claim)

From 65 (normal retiring age) Up to 33/60ths (i.e. 25/60ths the pension which would have been payable if at the date of the loss he had attained normal retiring age, plus up to 8/60ths for added years at the discretion of the compensating authority)

A medical officer of the same age and service who had suffered diminution of emoluments by say £200 per annum could receive compensation calculated in the same way as a fraction of the £200 only.

## INSURANCE ACTS COMMITTEE

### ITS FUTURE DESIGNATION

A meeting of the Insurance Acts Committee was held on July 8 with Dr E. A. Gregg in the chair its first business being to consider the designation and constitution of the committee itself under the new set-up. The first question was about the organization of its electorate and whether the organization should be on parallel lines with that recently decided for the representation of consultants and specialists. Should the representation be on a regional-board or executive-council area basis? The opinion was stated that the regions, which cut across local-authority and executive-council boundaries, were ill adapted to the representation of general practitioners and that although the reconstituted committee would function for general practitioners in much the same way as the Consultants and Specialists Committee would function for its constituents there was no need to have parallelism in territorial representation. The number of specialists was relatively small and could not have local medical committees in the same sense as general practitioners could have them in executive-council areas.

At the same time the 'regional' idea found some support one member saying that he hoped the time would come when general practitioners would be associated much more closely with the hospitals and therefore unless the group machinery were shown to have great advantages over the regional he would support the latter if only for that reason.

The Secretary (Dr Charles Hill) pointed out that the regional method had one small administrative advantage in that there were to be on the regional consultants' committees representatives of the local medical committees in the region, otherwise the method had many disadvantages. He suggested that the existing arrangement which held good for the election of the Insurance Acts Committee should be continued for the present and a change made later if this was considered desirable.

It appeared that the majority of the committee were in favour of the present group system for election, based upon local medical committees the successors of the panel committees and this plan was agreed to on the understanding that it might be amended in the light of experience.

### Name of the New Committee,

Various suggestions were put forward for the name of the newly constituted committee. One was that it be called the 'Central General Practitioners Committee,' which conveyed exactly what it would be. Another was 'Health Service General Practitioners Committee.' In the interests of brevity the term 'Central Medical Committee' found some favour but it was pointed out that such a committee would be presumed from its title to have a much wider field than in fact it would cover.

After some discussion it was agreed that the title should be the 'General Medical Services Committee.'

### Local Medical Committees

The committee then turned to the question of the constitution and election of local medical committees, a draft model scheme

of which had been put forward by the General Practice Sub-committee of the Negotiating Committee. General approval was given to this scheme, subject to the inclusion of a provision for a postal vote and to a reconsideration of a matter of procedure concerning the filling of vacancies. This model scheme has been circulated to local medical committees with an urgent request for early elections. It was agreed also to suggest to local medical committees that the power to co-opt additional members, which is proposed in the draft model scheme, might be used for the purpose of bringing in any medical member of the local executive council nominated by the committee.

### The Minister's Recent Speeches

Attention was drawn by Dr Wand to a speech by the Minister of Health at Preston on July 5, as well as on other occasions which contained a misleading reference to two million persons who had not yet 'registered,' and made some people believe that they were liable to a heavy fine if they did not place themselves on doctors' lists. Further, in a circular which an employee of a local authority had received it was stated that he must join a doctor's list because an official certificate would be required if he was absent from work owing to illness. Dr Wand urged that the utmost publicity should be given in the Press to the patient's rights in the matter of joining a doctor's list.

### Medical Cards

A protest was made by some members of the committee that the medical cards which were being issued did not give effect to any of the Medical Card Subcommittee's recommendations for alterations of wording.

The chairman explained that the new medical card was prepared some time before the subcommittee's proposals were made, but owing to the suspension of negotiations between the profession and the Ministry, the Ministry, stating that the matter was urgent, found itself compelled to proceed without awaiting their views. These views had since been communicated to the Ministry, but the printing of the card had already proceeded. After some discussion, in which several members made protests on the subject one of them pointing out that according to the instructions on the card a patient could change his doctor immediately he wanted to do so, the following resolution was adopted:

That the Insurance Acts Committee are dissatisfied with the results of their representations to the Ministry of Health on the subject of medical cards, and request the appropriate committee to press strongly for urgent revision of the "General Information" section of the medical card.

### Other Business

The committee expressed itself in agreement with a resolution from the Derbyshire Local Medical Committee that where it had memoranda, reports, etc., for submission to statutory bodies concerned with the national Service such documents should be submitted where possible to its constituent committees for approval or amendment.

The committee expressed itself in favour of a levy (voluntary or statutory) for the purpose of financing local medical committees.

The Rural Practitioners' Subcommittee was requested to formulate its views on the question of general practitioners in relation to specialist services rendered by them in cottage hospitals.

### TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union, or other organization:

*Metropolitan Borough Councils*—Fulham, Hackney, Poplar

*Non-County Borough Councils*—Dartford, Radcliffe (limited to future appointments), Tottenham, WallSEND

*Urban District Councils*—Denton, Droylsden, Houghton-le-Spring, Huryton-with-Roby, Portslade, Redditch (restricted to new appointments), Tyldesley

## HEARD AT HEADQUARTERS

### Clean Sheets

A pleasant but by no means a new compliment to National Health Insurance practitioners appears in the annual report, just issued, of the Ministry of Health. The report states that during the year under review the service continued to function efficiently and to meet requirements satisfactorily, as indicated by the small number of complaints made by insured persons and by approved societies against medical practitioners working the Act. During the year the sum of £119 was withheld from fourteen doctors for breaches of the terms of service. That £119 needs to be considered against the background of £15,200,000 which represents the remuneration of practitioners in England and Wales, and the fourteen substantiated complaints against the figure of eighteen and a quarter million people on practitioners' lists. During this same year no inquiry was called for in consequence of representations that the continuance of a practitioner in the service was prejudicial to the interests of the insured. It is a pretty good record. Hard things are still sometimes said about those who are still called "panel doctors," usually by those who have never been insured patients, and some of the prejudice carries over into the new Service, so that it is just as well to have it from the horse's mouth in Whitehall that, judged at any rate by this negative test, the service is a jolly good one.

### Dentists at Variance

A curious case occupied the Dental Board at its recent sitting and is worth putting on record. Two prominent dentists, having an address in the West End of London as well as in Hertfordshire were summoned before the Board on the complaint that they had advertised for the purpose of obtaining patients or promoting their professional advantage by the issue of a circular to a number of persons. The circular stated that "Mr — and Mr — wish to inform you that, under strong protest, but in the interests of the unity of the profession, they have finally acceded to the wishes of their colleagues in the locality and will in future be unable to accept National Health Insurance letters. To those patients, however, who would normally present such letters they will be happy to render their professional services at any of their surgeries on payment of a fee equivalent to the proportion which would have been paid by the patient under National Health Insurance." The complainants were nine other dentists, two of whom gave evidence, as did both the respondents. After a lengthy hearing and deliberation *in camera* the Board came to the conclusion that the facts alleged had not been proved to its satisfaction and discharged the case.

### The Plague of Initials

Mr Zachary Cope, in his address to the International Students' Clinical Congress, made an amusing reference to the manner in which the English language nowadays, including medical language, is contracted to initials. Initials, as he rightly said, are a dreadful form of language, and yet in medicine they flourish like weeds. Mr Cope gave the following example, which he did not claim to be authentic: "One of the members of the ISCC part of the IUS, who took the MRCS, LRCP, MB, BS, was a B1 at UCH, and although not C3 in health, but in fact almost A1, he wrote to the BMJ at the BMA asking if the MRC in UK or the NRC in US had notes on BCG in the treatment of TB." It was suggested that the proper answer was "O.K." The students at their congress, by the way, which lasted 17 days, spent a strenuous time. Their itinerary for just one day at Oxford was as follows: 10 a.m., lecture on analgesia in childbirth, 11.30, lecture on tuberculosis in the boot and shoe trade, 2.30 p.m., lecture on blood diseases, 5.0, lecture on blood coagulation, and then, after dinner in Magdalen Hall, three discussion groups on medical training.

Regulations have been made providing for interchangeability of service with preservation of superannuation rights between English and Scottish health services, and between either of the services and the Local Government Service and the Teaching Service.

## National Health Service News

### Compensation for Loss of Right to Sell Goodwill

The Ministry of Health states that doctors who retired from practice or the personal representatives of doctors who died between the date of the passing of the Act (Nov. 6, 1946) and July 5, 1948 and whose practices have not been sold in whole or part by July 5, 1948 should make early application to the Secretary, Medical Practices Committee, Devonshire House, Mansfield Place, Piccadilly, W1 for a certificate that the conditions laid down in Section 37 of the Act are satisfied. If the conditions are satisfied a claim for compensation for the loss of the right to sell the goodwill of the practice may be made on a form which the committee will supply. The completed claim form must be sent to the Ministry of Health by Oct. 31, 1948. Doctors on medical lists on July 5, 1948 will receive a claim form from the local executive council for the area in which they reside. Any doctor who does not shortly receive his claim form should apply to his executive council.

### Doctors Dispensers

The Ministry of Health has had under consideration the position of doctors dispensers whose employment has terminated following the coming into operation of the National Health Service. Some of them have passed the examination of the Society of Apothecaries for assistants in dispensing, others have been trained in the R.A.M.C. or Royal Navy as sergeant compounder or sick berth petty officer, others have had long experience with doctors or in retail pharmacy. They may be regarded as capable of dispensing medicines in both retail and hospital practice under the supervision of a pharmacist.

Under the provisions of the Control of Engagements Order designated dispensers will generally register for employment with the local offices of the Ministry of Labour and National Service who have made special arrangements for handling these cases. Hospitals and retail chemists who need the services of experienced assistants are therefore advised to notify any vacancies to the Ministry of Labour local offices.

## Correspondence

### Superannuation Scheme

SIR—I have read with considerable interest the article "Reflections on Superannuation" by Mr. A. N. Dixon (*Supplement* July 3 p. 23). This is a very excellent contribution on a subject which is undoubtedly puzzling a great number of practitioners.

In my capacity as Midlands branch manager of a life assurance company I received requests from a considerable number of our doctor policy-holders in the Midlands for clarification. An advisory service was opened to give advice to practitioners on the implications of the alternatives of the two schemes. Between June 20 and July 5 my staff and I had the opportunity of discussing this question with well over 100 doctors. The great majority were completely in the dark, because in certain cases they had not at that time received the official explanatory booklet and also up to June 30 only one or two isolated practitioners had received the Form SDD. (Fortunately both these documents were in possession by June 24.)

(1) Any practitioner who was not already paying the qualifying premium of £50 per year had the afore-said very limited time in which to make a decision to stay in or out of the scheme and many will of course be reluctant to joining the State scheme compulsorily.

(2) In our discussions with doctors we have endeavoured to give them on somewhat the same basis as outlined by your correspondent and as we are very anxious indeed to be completely fair and explain the pros and cons accurately, there are certain points in your correspondence which could assist us in confirming.

(3) Your correspondent indicates a 2.5% tax relief on £5-0-0 per year of a premium of £150. Has the tax position been definitely decided by the Inland Revenue authorities? If so on what basis is the 2.5% determined?

To satisfy the condition for opting out a policy of a suitable period can be either an endowment assurance or a deferred annuity contract. The Inland Revenue authorities do not normally allow relief of tax on deferred annuity contracts to individuals except through an authorized staff pension scheme, they do allow relief of tax on endowment assurances. To a doctor who has been paying a sufficient premium on an endowment assurance the Government will allow an amount equivalent to 8% of income which is the same amount as its contribution would be under the superannuation scheme. Is it maintained that a doctor with an endowment assurance must lose the greater part of the tax relief he was receiving before the National Health Service commenced while a doctor with a deferred annuity contract loses nothing? This is inconsistent with the Government's encouragement of the paying of life assurance premiums.

(b) There seem to be very divided opinions among those people who have given this matter considerable thought as to the income tax position. It would be in the interests of practitioners if the income tax position of both the employees' and employers' contributions were clarified by the Inland Revenue or authoritative information published in your *Journal*.

(c) In the list of tabulated figures Mr. Dixon quotes "a return after the first year of £72 after the 3rd year £223." I would like to ask Mr. Dixon if he has overlooked the fact that these contributions are returned with 2½% compound interest but less income tax and with income tax at its present rate of 9s. in the £ these cash returns would be sadly reduced.

(3) In the tabulation figures in the article Mr. Dixon refers to the pension payable at the age of 65 from the capital proceeds of the life assurance policy. If this capital sum is used to purchase what is known as a split guaranteed annuity, the income would not only be guaranteed to the doctor for life but to his estate for certain for 10 years after age of 65, and he would also for the first 10 years enjoy a much reduced income tax charge. This method of pension is calculated in two parts: (a) return of the capital and (b) a deferred annuity. The capital return is not taxable, the interest portion only being taxable. This means that averaged over the 10 years about 7/8ths of the pension is free of income tax. There will be many cases where such a pension will provide a higher net income after age 65 than the pension under the superannuation scheme would do. The fact that this guaranteed annuity is payable for 10 years at least after age 65 is a most valuable safeguard for a dependant.

(4) Your correspondent dismisses the injury pension and benefits for incapacity very briefly because they "provide for contingencies so remote as to carry little weight in the general balance." These contingencies may be remote, but when permanent incapacity does occur it is the worst thing that can happen to a professional man. There are undoubtedly a great many doctors who are more concerned about providing for that contingency than they are about death itself. It is in fact, economic death. It could be argued that the chance of any particular house being burnt down is remote, but few neglect to take out fire insurance. It is well that the ordinary scheme makes some provision for incapacity in the later years. In any alternative arrangement the advisability of covering permanent incapacity in the earlier years is certainly worthy of consideration.

(5) As under the present regulations it is possible to provide a tax free pension for a widow to cover all the years between death of the doctor and the retirement year (age 65) this deserves consideration by doctors who would like to close the greatest gap of all in the State superannuation scheme. At the end of this income-paying period the widow would have a lump sum with which to buy an annuity.

(6) The special benefits mentioned in parts 3, 4, and 5 are part of the modern developments of life assurance, and can be obtained from most of the progressive life offices.

(7) It is felt that the decision to accept the scheme or to "opt out" should be taken only after very careful consideration of all the facts. It is an individual problem and should be investigated fully by every practitioner.

—I am, etc.

Birmingham

R. N. YOUNG

\* We have shown this letter to Mr. A. N. Dixon, whose reply is printed below.—Ed. B.M.J.

SIR—I am grateful to Mr. R. N. Young for raising a number of points all of which are of interest and one at least—the income tax position—is fundamental. I should have liked to have enlarged on all these and certain other issues in the original article, but, considerations of space apart, I concluded that the subject was already sufficiently technical and that further details might only confuse the issue. Perhaps it would be most satisfactory if I now deal with Mr. Young's points in the order in which they arise.

(1) I entirely agree with him that earlier notice would have been most desirable and there is no doubt that many difficulties would have been avoided if earlier information had been made available. However, I must confess that, reading between the lines, I feel the Ministry never intended that there should be any alternative to the superannuation scheme in the sense that any doctor could make a personal choice in the matter. I believe that the option was allowed purely to provide for the practitioner *already committed* to premiums which might possibly prove inconvenient, and who might otherwise have been financially prejudiced. If this interpretation is correct, then the lack of notice affects only those whom it was never intended to assist, and not much real damage has been done.

(2) (a) and (b) At the time of writing the article the tax position in regard to the Government's 8% contribution to assurance was not clear, and even now there are conflicting views on the position. Therefore some assumption had to be made, and in my view the only equitable basis on which to proceed was to assume that, in relation to the *Government's contribution* a practitioner should not be worse off under an agreed parallel alternative than under the superannuation scheme itself—i.e., that in no circumstances would he be expected to bear income tax on the *Government's contribution*. Equally clearly he could not expect to claim tax relief on that contribution, and the figures to which Mr Young refers are explained accordingly. It has now been suggested that the Government's 8% contribution to approved life assurance will be aggregated to income and so become subject to tax. Whatever the ultimate outcome, I submit that this arrangement is wholly inequitable, but practitioners must proceed warily and take this contingency into account. Obviously it adversely affects the assurance comparison, but, if it is enforced, then of course the whole premium (i.e., £150 in the example) becomes subject to tax relief at the two-fifths rate.

Broadly, I think it will still be found that up to retirement age the assurance method provides an appreciably better result, but that, on retirement, pension benefits will be even more markedly in favour of the Government scheme.

As regards the question of deferred annuity contracts, Mr Young's argument is sound so far as it goes, but he may not be aware of the B.M.A. and National Health Insurance Practitioners' Pension and Insurance Schemes, which are basically a form of deferred annuity combined with family provision, and which have been "approved" by the Inland Revenue. An enormous number of these policies are in being and no doubt it was to cater for this position and possibly also for the practitioner no longer able, on medical grounds, to secure life assurance, that this deferred annuity provision was inserted. Obviously no encouragement would be given to opting out purely on deferred annuity lines, for is not a deferred annuity almost exactly what the superannuation scheme itself so very efficiently provides?

(c) It is agreed that in the figures quoted tax has not been deducted. I have been unable to trace in the regulations any reference to the application of such a deduction *in the case of death* and so I omitted it from my calculations. At this stage in the table the comparison is so overwhelmingly in favour of the life assurance method that any further reduction in the figures of the superannuation scheme is almost superfluous, even if established.

(3) In considering the question of pension I had not overlooked the advantages of the "split guaranteed annuity," an arrangement quite familiar to me, but in writing the article I had set absolute impartiality as a first principle. It was essential, therefore, strictly to compare like with like, and this is not quite the case in Mr Young's example. Under the superannuation scheme a pension is payable throughout the lifetime of the male and one-third of that amount *throughout the lifetime of the wife* if she is the survivor. By the split annuity method, payment is made for ten years certain and then so long as the male shall live. Therefore it does not protect the widow if she survives the male for more than ten years from *original retirement*. Taking into account probable disparity in age and known favourable female mortality, this is not only possible but likely. There are two further reasons why I did not bring in the split annuity method, the first is that, while this arrangement is permitted by the Revenue at the present moment, it does not follow that such will be the case in future, and,

secondly, neither does it follow that saving of tax necessarily arises in every instance. In the lower pension groups, where the full incidence of tax is not felt, it is questionable whether this method shows any advantage over the normally higher immediate annuity, because only the lower rates of tax, and possibly no tax at all, may apply. In any event, it is open to the practitioner to take his capital and use it in whichever manner is found to be the more advantageous at the time.

(4) Your correspondent mentions that I dismissed too lightly the "injury pension and benefits for permanent incapacity." If he will refer again to the article I think he will find that he has confused the position. What I really dismissed were "injury pension," "short service gratuity," and "return of contributions," *not* "permanent incapacity." I still maintain that "injury pension" (which can arise only from injury in the discharge of duty) is remote. Permanent incapacity may arise from a variety of ills, but this is covered under the normal "pension" section, and that is a valuable cover. However, this is not to say that no gap exists, because clearly it does. Permanent disability is covered (for pension benefit) after ten years' service, but thereafter the earlier pension scales are somewhat inadequate, and of course there is no benefit for temporary incapacity. I feel most strongly that both the entrant into the scheme and the "opt-out" should cover these liabilities, and in fact I stress it in the latter part of the article.

Finally, I am in complete agreement with your correspondent that the decision to opt out should only be taken after the most careful consideration and that it is purely one for the individual himself. For my part, I tend more and more to the view that in the majority of cases, and making due allowance for the income tax position, it is desirable to enter the scheme and then to cover the obvious gap by external assurance arrangements—I am, etc.,

Medical Insurance Agency

A. N. DIXON,  
Manager

SIR—May I in one letter reply to the letters of Dr Bernard Samuels and Dr T. J. Cronin (*Supplement* July 17, p. 49) and also comment on the article on superannuation in N.H.S. (p. 47)? Dr Samuels is quite wrong. The Superannuation Regulations are not so difficult to follow if we pay strict attention to the precise definitions given in the first pages. They bestow upon us considerable benefits, for in the long run we get back not only the 6% deductions but also the 8% contributed by the employing authority. The benefits are equivalent to an increase of from 12% to 20% in the capitation fee, the higher figure applying where the remuneration falls within the first range of surtax.

Advice to Dr Cronin and all other practitioners under 60 leave the life assurance option alone, even if it means increasing your overdraft. It does not appear to have been pointed out that this concession is completely upset by income tax considerations. In the superannuation scheme neither the 6% nor the 8% will be subject to income tax, so that if a practitioner's remuneration after allowing for expenses is £100 his income tax will be assessed on £94 and £14 will be placed in the fund for his benefit. If he takes the option and draws the £8 to pay his policies, his income tax will be assessed on £108; he will get only the usual policy allowance. This will usually mean that he loses £6. The option is of interest only to the who will have less than five years' contributory service whose premiums are sufficiently large to take up the whole the 8%. So it is of no interest to anyone under 65 unless he does not intend to avail himself of the extension of pensionable age and complete five years, and it is of interest to him only because, having less than five years' contributory service, he loses the benefit of the 8%, getting back only his own 6% contributions.

The extension of pensionable age is a most important regulation. Without it the distribution curve of benefits shows very objectionable singular points occasioned by the qualifying periods. Thus, without the concession a practitioner who was 5 on July 4 would have drawn only two thirds of the benefits which his contributions and those made by the employing authority on account of his services would meet, and of this amount 40% would not be paid in his lifetime. His more fortunate colleague born two days after him would draw 50% benefits than the corresponding contributions would meet. It is difficult to understand why these qualifying periods

of a Division was informed firmly by a large area distributor that his firm gave no preference of any kind to doctors. As regards my own position, inquiry to-day of my agent brings the encouraging news that at the present rate of delivery my car, ordered in July, 1946, may be expected in 8½ years. In these circumstances one may well agree with the advice that doctors should not refrain from placing an order until their car is on its last legs.

Incidentally, have Messrs Cooke and Grafton advised the members of their respective bodies who have accepted a deposit from those ordering cars to return this on request now that this "deposit racket" has been officially disapproved?—I am, etc.,

### A Provocative Minister

SIR—At the time of our first plebiscite the Minister of Health was misguided enough to suggest that much of the opposition which he was meeting from the medical profession was inspired by the Tories—this in spite of the fact that the Tories had pledged themselves to support a national health service which ever Government proposed to introduce it. The Minister's remarks caused considerable anger in the profession at the time, and he was sensible enough to refrain from any further remarks in this vein till Sunday, July 4, at Manchester, when on the eve of the full implementation of the Health Service Act he chose to launch a most violent and bitter attack against the Tories. The fact that he chose such a time to make such remarks may have been a mere coincidence but, although it is my opinion that doctors should not be engaged actively in politics, it would appear as if we will have to be very careful from now on as to where and when we express our political views should such views in any way differ from the professed politics of Mr Bevan.

That such a state of affairs is probable can only cause the gravest of doubts—perhaps they were already there in the minds of many of us—as to the true intentions of Mr Bevan and his political colleagues. We have heard much from the gentleman on the vexed question of the Press and its "prostitution". Unless we are very careful our noble profession will soon be on the down-road to a similar fate.—I am, etc.,

Bridlington

M A LINELL

### Professional Secrecy

SIR—Dr Arthur and the Gateshead Division are, I submit, to be congratulated (*vide Supplement* July 3, p 14) on their protest against the serious threat to professional secrecy foreshadowed in the increasing tendency to disclosure to lay persons by Government departments of professional confidences contained in medical certificates. Using his powers under Section 66 of the Act the Minister of Health has issued Regulations (Statutory Instruments 506 and 507, 1948, dated March 24, 1948) of which Section 14 (No 507), occupying 62 lines, makes detailed rules for the compilation and inspection of medical records to be kept by the practitioner of public patients as distinct from private patients, and the importance attached by the Minister to this new obligation is demonstrated in every line of the section.

The duty of the doctor in the State Service to compile and furnish full medical details of public patients under his care was insisted upon throughout the passage of the Bill and to enable him to do so generous clerical assistance was to be supplied to the doctor as part of the service given by the health centres. This provision is temporarily suspended, but a new committee, the Medical Service Committee, consisting of a lay chairman, three lay members of the local executive council, and three members of the local medical committee, is charged with the duty of investigation and supervision of record keeping and in the absence of health centres (where records were to have been housed) "access is to be given to the committee at all reasonable times to the practitioner's surgery or other place where record cards are kept, for the purpose of inspection of such record cards". The practitioner may be further required to furnish to members of the committee "any such record cards and any necessary information with regard thereto as they may require". The committee shall report to the Minister where there has been any failure on the part of the practitioner to carry out these exacting obligations and such action shall be

taken by the Minister as "the extent and gravity of such failure may warrant. I imagine that Dr Arthur and the Gateshead Division had not noted these Regulations, examination of which would have materially supported their protest.—I am, etc.,

House of Commons

E GRAHAM-LITTLE

### Hospital Superintendents

SIR—At the annual meeting of the R B it was reported by Dr MacArthur (*Supplement* July 3, p 17) that a memorandum had been circulated 'to all committees of management (without previous negotiation and consultation with the leaders of the profession) instructing them that they should appoint secretaries whose duties and powers made them the superior of the medical superintendent from the point of view not only of his power and authority but also of the scale of salary'.

It was proposed and seconded that before any final settlement is arranged with the Government the B M A should insist that the principle that the medical superintendent is recognized as the administrative head of the hospital be maintained. There was no dissentient to the motion, and yet the chairman of the Hospitals Committee intervened to suggest that the matter be referred to the Council, which was adopted. He stated that it was the policy of the Association that the administrative head of a large hospital or group of small hospitals should ordinarily be a medical practitioner and designated as medical superintendent and that the negotiating committee had discussed it with the Ministry.

It is evident that the drafters of the memorandum quoted by Dr MacArthur have ignored the policy of the Association and therefore the adoption of the motion was entirely justified. As a past medical superintendent of many years' experience I shall, however, be surprised and gratified if even as strong an action as this would have any effect on the determination of the Civil Service, as evidenced by the memorandum, to subordinate the profession to lay officials. One may wonder what the reaction of the Admiralty would be to the suggestion that the supreme authority in a ship should be not a sailor but one of the clerical staff!—I am, etc.,

St Mawes Cornwall

B H SHAW

### A R M Correction

SIR—May I beg the favour of some of your space to correct the report of what I said at the A R M (*Supplement*, July 3 p 8)? The Division I represent is given in an anatomical variant of its name (St Pancras). Further, it is incorrect to state that at the meeting of the Health Committee of the TUC to which I referred it was said from the TUC side that the only organization which represented the medical profession was the B M A. That was not the statement made on that occasion. The statement was that "the British Medical Association was recognized as the organization which represented the medical profession". The words reported may represent in condensed form a natural interpretation of what I said in my speech in the light of the whole of the speech, or may indeed be due to my having expressed myself badly, and if so I should like to correct it.

Finally, at the end of the speech the word 'not' is omitted in the report. The final words should be 'He was by no means satisfied that the Association was in the legal position described in which it could not carry on negotiations, discussions and activities to their full logical length without seriously involving itself in the likelihood of a legal disaster'.—I am, etc.

## Association Notices

### Meetings of Branches and Divisions

#### DUMFRIES AND GALLOWAY DIVISION

The Annual Summer Meeting, under the chairmanship of Mr R L Beveridge, was held at Newton Stewart on July 11. The meeting was addressed by Dr A K Bowman, Senior Medical Officer to the Western Regional Hospital Board. The address was in two parts, the first being on American medicine and medical personalities and the second on some historical aspects of the early colonization of America. Dr Bowman was interesting and informative and he took the opportunity of pleading for better understanding between this country and America, and for the acceptance of Marshall aid in the spirit in which it is being given. Dr Clayson proposed a vote of thanks at the end of the meeting.

## ANTI-HISTAMINE SUBSTANCES\*

BY

SIR HENRY DALE, OM, GBE, FRCP, FRS

As one of those who took part in the recognition of histamine in nature and in the first detailed examination of its intense physiological activities, I shall try to avoid the temptation to be unduly reminiscent. I may just remind you that at that time, nearly 40 years ago much interest in circles concerned with experimental pathology was centred on the syndrome of the anaphylactic reaction and on the curious differences which it presented in the different species. You can imagine that Laidlaw and I (Dale and Laidlaw 1910, 1911) had to discipline our eagerness as we examined one by one the actions of histamine on the different organs and systems of the dog and the guinea-pig in particular, and found them fitting neatly, like units of a jigsaw puzzle, into the contrasting pictures of the anaphylactic reactions in those two species as others had then recently described them. Biedl and Kraus (1910) had already drawn attention to the close correspondence—even closer, in fact—between the contrasted reactions of the normal dog and guinea-pig to intravenous Witte's peptone and those of the anaphylactic dog and guinea-pig to the reinjection of the antigen. I well remember Biedl's account of this at the International Physiological Congress in Vienna in 1910 and my own description later in the same programme of the newly discovered and, except for a few points, identical effects of histamine on the same two species. There was, of course, an obvious probability that a correspondence at so many points would have some significance but it was difficult to guess just what it might mean. It certainly did not mean, what some were too ready to assume, that histamine was the hypothetical "anaphylatoxin" of which there was then so much talk, as a poison supposed to be liberated in the blood by some kind of enzymatic cleavage of the reinjected antigen, for there were features of the anaphylactic and peptone shocks which were not represented in the actions of histamine such as the gross swelling of the liver and the failure of the shed blood to clot, and Laidlaw and I thought, and said, that these gaps must be taken into account in any discussion of the meaning of the general correspondence.

That of course, is ancient history, and a great deal has happened since to clarify what was then obscure. Fortunately there have been several most valuable reviews of the all too abundant literature. I may mention the monograph of Feldberg and Schilf in 1930, Gaddum's (1936) monograph on vasodilator substances and quite recently a review-lecture by Gaddum (1948), full of suggestive thought, dealing chiefly with later and contemporary work. Let me just indicate what seem to me a few of the landmarks of progress on the way to the present position and then mention certain outstanding problems which seem to be

worth further attention, if only to provide us with a more completely rational basis for the use of the so-called anti-histamines with which to-day's discussion is largely concerned.

### Landmarks of Progress

First, as to the pharmacological action of histamine, I suppose that we shall now agree that it is a general stimulator of the tone and rhythm of plain muscle in most mammalian species, the *Muridae* presenting an exception and then that the vasodilator-depressor action which it produces so conspicuously on intravenous injection into certain species, including the human, is due to a special inhibitor action on the tone of minute blood vessels, involving always the tone of the capillaries and extending in some species, man among them, but to different levels in the different species, on to the ultimate arteriolar branchings. The involvement of the capillaries, and the resulting permeability of their walls if the action is powerful, came to light when Laidlaw, Richards, and I resumed the study of the action of histamine in the middle of the first world war under the stimulus of the demand for any light which experimental work could throw, even obliquely, on the obscure problems of wound shock, a demand which was naturally revived in the second world war. Concerning our work (Dale and Richards, 1918, Dale and Laidlaw, 1918) in 1917-18 I should just like to note, in passing, the useful and stimulating coincidence with our conclusions at that juncture of those reached by others who were then working on similar reactions. Krogh (1929), as we learned a little later, was already engaged on his more general study of the variable tone of the capillary vessels. Lewis, Cotton, and Slade (1917) had already published a year earlier the initial stage of what became Lewis's classical studies of the "threefold reaction" of the small blood vessels of the human skin to various injuries and, still more aptly for our immediate purpose Sollmann and Pilcher (1917) had just shown that application of histamine itself in high dilutions to the human epidermis after microscopic breaches of its surface caused local capillary dilatation and weal formation. We ourselves being impressed by the analogy, pointed out that a not too destructive local injury, such as a blow from a whip or cane would produce a closely similar local vascular effect just as the generalized effects of histamine on the blood vessels which we were describing resembled those of a generalized tissue injury.

What was known of the pharmacological actions of histamine was thus already sufficient to arouse a suspicion that its release in response to injury of tissue cells might account for a substantial part at least of the resulting vascular and other reactions, whether the injury was produced by mechanical trauma, by corrosive or precipitant

\*Read in opening a discussion in the Section of Pharmacology at the Annual Meeting of the British Medical Association, Cambridge, 1948.

chemicals, or, in an anaphylactic subject, by the specific antigen. For by that time I think it was generally agreed that the anaphylactic condition was due, at least in the main, to the predominant attachment of a precipitating immune substance to the tissue cells, and that the different symptomatology of the shock in different species was due to the way in which this sensitizing antibody was allocated among the cells of the different organs—being mainly attached to those of the liver of the dog, and mainly to those of plain muscle in the guinea-pig. We were not yet entitled, however, to indulge in any definite theories about such a release of histamine, since we had no real evidence so far that it was a constituent of normal tissue cells; we had only the early finding of it by Barger and myself (1911) as a constituent of intestinal mucosa, which we could hardly regard as a typical tissue for this purpose. Most of a further decade was required, then, before the evidence from different sources once again converged to a new point of advance. We had the resumption of the brilliant series of experiments, chiefly on human skin, by Lewis and his team, producing cumulative evidence of the release by the various kinds of mild injury of something having all the observable properties of histamine, but always by them called "H-substance" with a truly scientific caution. I think there can be little reason to doubt that they were dealing with histamine itself, either free or in loose association with some more complex vector.

I suppose that everybody working with this group of phenomena had in mind the possibility that the effect of the specific antigen on the cells of the anaphylactic animal might be to cause histamine to appear. I, rather perversely perhaps, had myself been inclined (Dale, 1919) for a time to discount it, pointing out that for aught we knew the action of histamine itself might be to produce an aggregating effect comparable to that which we had reason to impute to the reaction between anaphylactic antigen and cell-fixed antibody. Abel and Kubota (1919) had favoured the idea that histamine was somehow concerned, but I believe that it was Lewis (1927) who, having seen a dermal allergic reaction and recognized the characteristic "threefold response," first definitely attributed the effect to the appearance of histamine, or, more strictly, "H-substance." It was at this point, however, that there was once again such a convergence of researches, for at that same period an irrelevant side issue had led me to organize with Best, Dudley, and Thorpe (1927) an effort to obtain unequivocal evidence regarding the nature of the substances with histamine-like actions extractable from different fresh tissues—liver first, then lung, then muscle, then spleen. In all cases it was histamine itself; detachable without any drastic treatment from more complex materials, its tendency to cling to which had apparently misled earlier workers. So that it did not seem necessary to suppose, as Abel and even Lewis had been inclined to do, that histamine was formed in response to injurious stimuli, including that of the anaphylactic antigen, or allergic haptene; it was there already, held inside the cell in inactive association, and we had only to postulate its release. And then that chapter seemed to be rounded off and completed when Dragstedt and his associates found histamine in the lymph flowing from the dog's liver in the anaphylactic shock (Gebauer-Fuelnegg, Dragstedt, and Mullenix, 1932), and Feldberg with his team found it appearing in the effluent from the perfused lungs of an anaphylactic guinea-pig (Bartosch, Feldberg, and Nagel, 1932) when the antigen was added to the inflowing saline solution and evoked the bronchial constriction.

All this evidence, of course, left it not only possible but practically certain that active and normally intracellular

constituents other than histamine would also be liberated with it. We know now, for example, that heparin is liberated from the liver by peptone or the anaphylactic reaction to make the blood incoagulable. Histamine, however, is by a long way the most potent in pharmacological action of any such cell constituents as are known, and it is the one which particularly concerns the present discussion. Let us consider, then, some points concerning the manner of its release which bear on our problem, and others on which more evidence would be of value.

### Mode of Histamine Release

1 Consider the relationship between the cells from which histamine is released—the sensitized cells on which the antigen or haptene acts in the case of the allergic reactions—and those which react to the released histamine, producing the familiar syndrome. The cells which release histamine and those which respond to it may be identical, as they probably are when sensitized plain muscle encounters the antigen, and we may plausibly picture this as a reaction to histamine internally liberated and speak of it as a response to *intrinsic* histamine. On the other hand, when histamine is released in the liver it is obviously carried widely by the circulation to other histamine-sensitive tissues, causing a general vasomotor collapse and stimulating the plain muscle of remote organs. Even when the injury releases histamine from epidermis or nasopharyngeal epithelium it is not the epithelial cells which respond to it but the subjacent vascular plexus, which thus reacts to *extrinsic* histamine. It will be clear that the antagonism of an antihistamine, whatever the precise mechanism of its action, may be widely different against histamine from within and histamine from without. There might obviously be analogies with the action of atropine in suppressing readily certain effects of acetylcholine applied from without while leaving practically unchanged corresponding effects of its release from nerve endings. There is an even closer analogy in Schild's observation that the guinea-pig's sensitized plain muscle can be made tolerant of excess of histamine in the surrounding fluid so that it gives no response to further additions of histamine to the bath but still responds to the specific antigen—presumably, therefore, to *intrinsic* histamine. Such considerations may throw light on the relative effectiveness of antihistamines in urticaria and vasomotor rhinitis on the one hand and in spasmodic asthma on the other. The point is at least worth discussion in the light of clinical experience of the relative values of these drugs in different types of allergic reaction.

2 I think that we need more evidence yet concerning the manner of the release of histamine which might furnish more details to show whether, when so liberated, it is in free solution or associated with larger molecules as an "H substance." Even if we accept the view that disturbance of the colloidal dispersion of the protoplasm liberates the histamine we still need more evidence whether it does so directly or by setting in action some enzyme system to which the actual liberation of histamine is due. Rocha e Silva's evidence that pure trypsin has this action is highly suggestive (Rocha e Silva and Andrade, 1945; Rocha e Silva, 1946), as are the earlier observations of Feldberg and Kellaway (1938) on the special factors concerned in the generally similar effects of cobra and bee venom. Kellaway's recent lecture (1947) gives a valuable review. We ought to know more, too, about the apparent new formation of "histamine" in scalded mice as recorded by Dekanski (1945).

3 We need still more information about the form in which histamine circulates in the blood. Estimates of histamine extracted from whole blood must, I think, be difficult.

to interpret physiologically. The blood is a tissue, and histamine held inactive in its cells need have no different functional significance from that locked up in the cells of solid tissues. Code's (1937) work in my laboratory seemed at the stage which it reached, to be pointing to the eosinophil cells as the source of most at least of the histamine extractable from normal blood, and, though it is also true that the abundant layer of platelets obtainable from citrated rabbit's blood seems to be the rich source in that species, I venture to suggest that a more critical haematology might throw light on the still rather curious anomaly that rabbit's whole blood yields so much more histamine than that of other common species. Another point which would, I suspect, repay further investigation is that of the possibility of the formation of histamine from proteins by hydrolysis, whether by enzymes or by heating with acids (cf. Abel and Kubota, 1919). I believe that it would be useful to have more definite evidence on the extent to which solutions containing "incoagulable" protein products can be heated with acid with a certainty that the histamine found in the product will be only that which was preformed in the original blood or other material.

4. Lastly it seems to me that it might have an important bearing on our conception of the proper and safe use of the antihistamines if the evidence for the concern of histamine in the vasodilatation of normal functional activity were clearer and more consistent. I raised the question of this in a possibility in a lecture in 1919, pointing out how the dilatation of capillary tone by histamine would make it the ideal agent of a fine adjustment of the circulation to local metabolic needs if we had evidence that it existed in the tissue cells and that it was liberated by their normal activity. We have evidence of its presence now, but the evidence produced by Anrep and his colleagues for its liberation from active muscle still lacks confirmation. I need hardly point out that failure to detect an increase of it in the venous blood does not of necessity exclude the possibility of its local liberation and local action. It might, however, suggest the possibility that in relation to antihistamines it would behave more like "intrinsic" than "extrinsic" histamine. In any case, I suggest that further attempts to settle the matter, perhaps by experiments under conditions not so close to those of natural circulation, might provide useful information, and that clear evidence on this point might give valuable warning or reassurance concerning the use of the antihistamines in practice.

## CAFFEINE AND GASTRIC SECRETION

BY

D. R. WOOD, M.A., B.M. B.Ch., B.Sc.

(From the Department of Pharmacology and Therapeutics, University of Sheffield)

The effects of caffeine on gastric secretion have recently been investigated in animals and in man by Roth and Ivy (1944a, 1944b, 1944c) and by Merendino *et al.* (1945). It has been shown that, although there is a wide variation in sensitivity between species, caffeine stimulates gastric secretion in man, cat, guinea-pig, and dog. Man is relatively sensitive to this action of caffeine, while the dog is rather resistant. The effect is probably exerted directly on the parietal cells.

Roth and Ivy (1944a) showed that the intravenous injection of 65–125 mg. of caffeine into cats anaesthetized with chloroform provokes a secretion of acid gastric juice for about 45 minutes. Later they reported (Roth and Ivy, 1944c) that caffeine and histamine act synergistically in stimulating gastric secretion in the cat. The effect was considerable, and in one animal a previously ineffective dose of histamine stimulated secretion of highly acid juice after injection of caffeine. The doses of caffeine used were themselves large enough to cause a secretion of acid gastric juice, and it was desirable to determine whether the effect of histamine was potentiated by smaller doses of caffeine which did not stimulate gastric secretion. This was particularly necessary, since doses of 125 mg. of caffeine are bordering on the toxic for the cat, and attempts to repeat the experiments of Roth and Ivy often resulted in early death of the animal. At the same time theobromine and theophylline have been compared with caffeine in respect of this relation to histamine.

## Methods

The cat, anaesthetized with sodium pentobarbitone intraperitoneally, was prepared for continuous drainage of gastric juice by Roth and Ivy's (1944a) modification of Lim's (1923) method. Ligatures were tied around the cardia and duodenum and a cannula was inserted into the stomach through the pylorus (see Wood, 1948). Juice was collected in graduated centrifuge tubes, and the free and total acid was estimated by titration with N/50 sodium hydroxide, using thymol blue as indicator for both end-points.

One hour after the completion of the preparation, secretion being basal (less than 0.05 ml. in 10 minutes), histamine acid phosphate was injected subcutaneously in a dose equivalent to 0.27–0.65 mg. of histamine (about 0.18 mg. per kg. of body weight). The resultant secretion of juice was measured at intervals of 10 minutes until the basal level of secretion returned.

The particular xanthine compound was then slowly injected intravenously over a period of two to five minutes. Solutions (1 or 2%) of caffeine sodium benzoate, theobromine sodium salicylate, and theophylline sodium acetate were used containing respectively about 1/2, 1/2, and 5/9 of caffeine, theobromine, and theophylline (w/w). Doses of caffeine were 10–20 mg. per kg. (20–75 mg. total dose), of theobromine 20 mg. per kg. (34–54 mg.), and of theophylline 20 mg. per kg. (42–62 mg.).

Two groups of experiments were done with caffeine. In one group of seven cats the second dose of histamine, the same as the first in any one cat, was injected 40–60 minutes after caffeine. This interval allowed enough time for any possible stimulant action of caffeine to pass off. Caffeine itself caused a significant increase in secretion in only three

of the seven cats. In another six animals the second dose of histamine was injected immediately after the caffeine. Collection of juice was continued until the basal level of secretion returned. The second dose of histamine was injected 40-60 minutes after theobromine or theophylline in all experiments with these substances.

### Results

**Caffeine**—Following the intravenous injection of 20 mg of caffeine per kg there was at first irregularity and some slowing of the heart and a transient fall of blood pressure. A temporary respiratory stimulation also occurred. Neither of these effects was so obvious after theophylline or theobromine, the blood pressure often rose about 10-15 mm Hg after theobromine. Both the magnitude and duration of the histamine stimulation of gastric secretion were increased after caffeine (Table I). This was observed in all 13 experiments. In three of the seven cats where there was an interval of 40-60 minutes between the injections of caffeine and of histamine there was a mild stimulation
